The AI team on Claude Code

Kanban Board 3.20.0. Everything on these pages was done by real Claude Code runs on Sonnet and Haiku, on a sample project: bugs fixed test-first in their own worktrees, a workflow from triage to review, a hang diagnosed and stopped, a PDF read from the knowledge base, a rule tried before it acted, and the Board AI acting by risk tier.

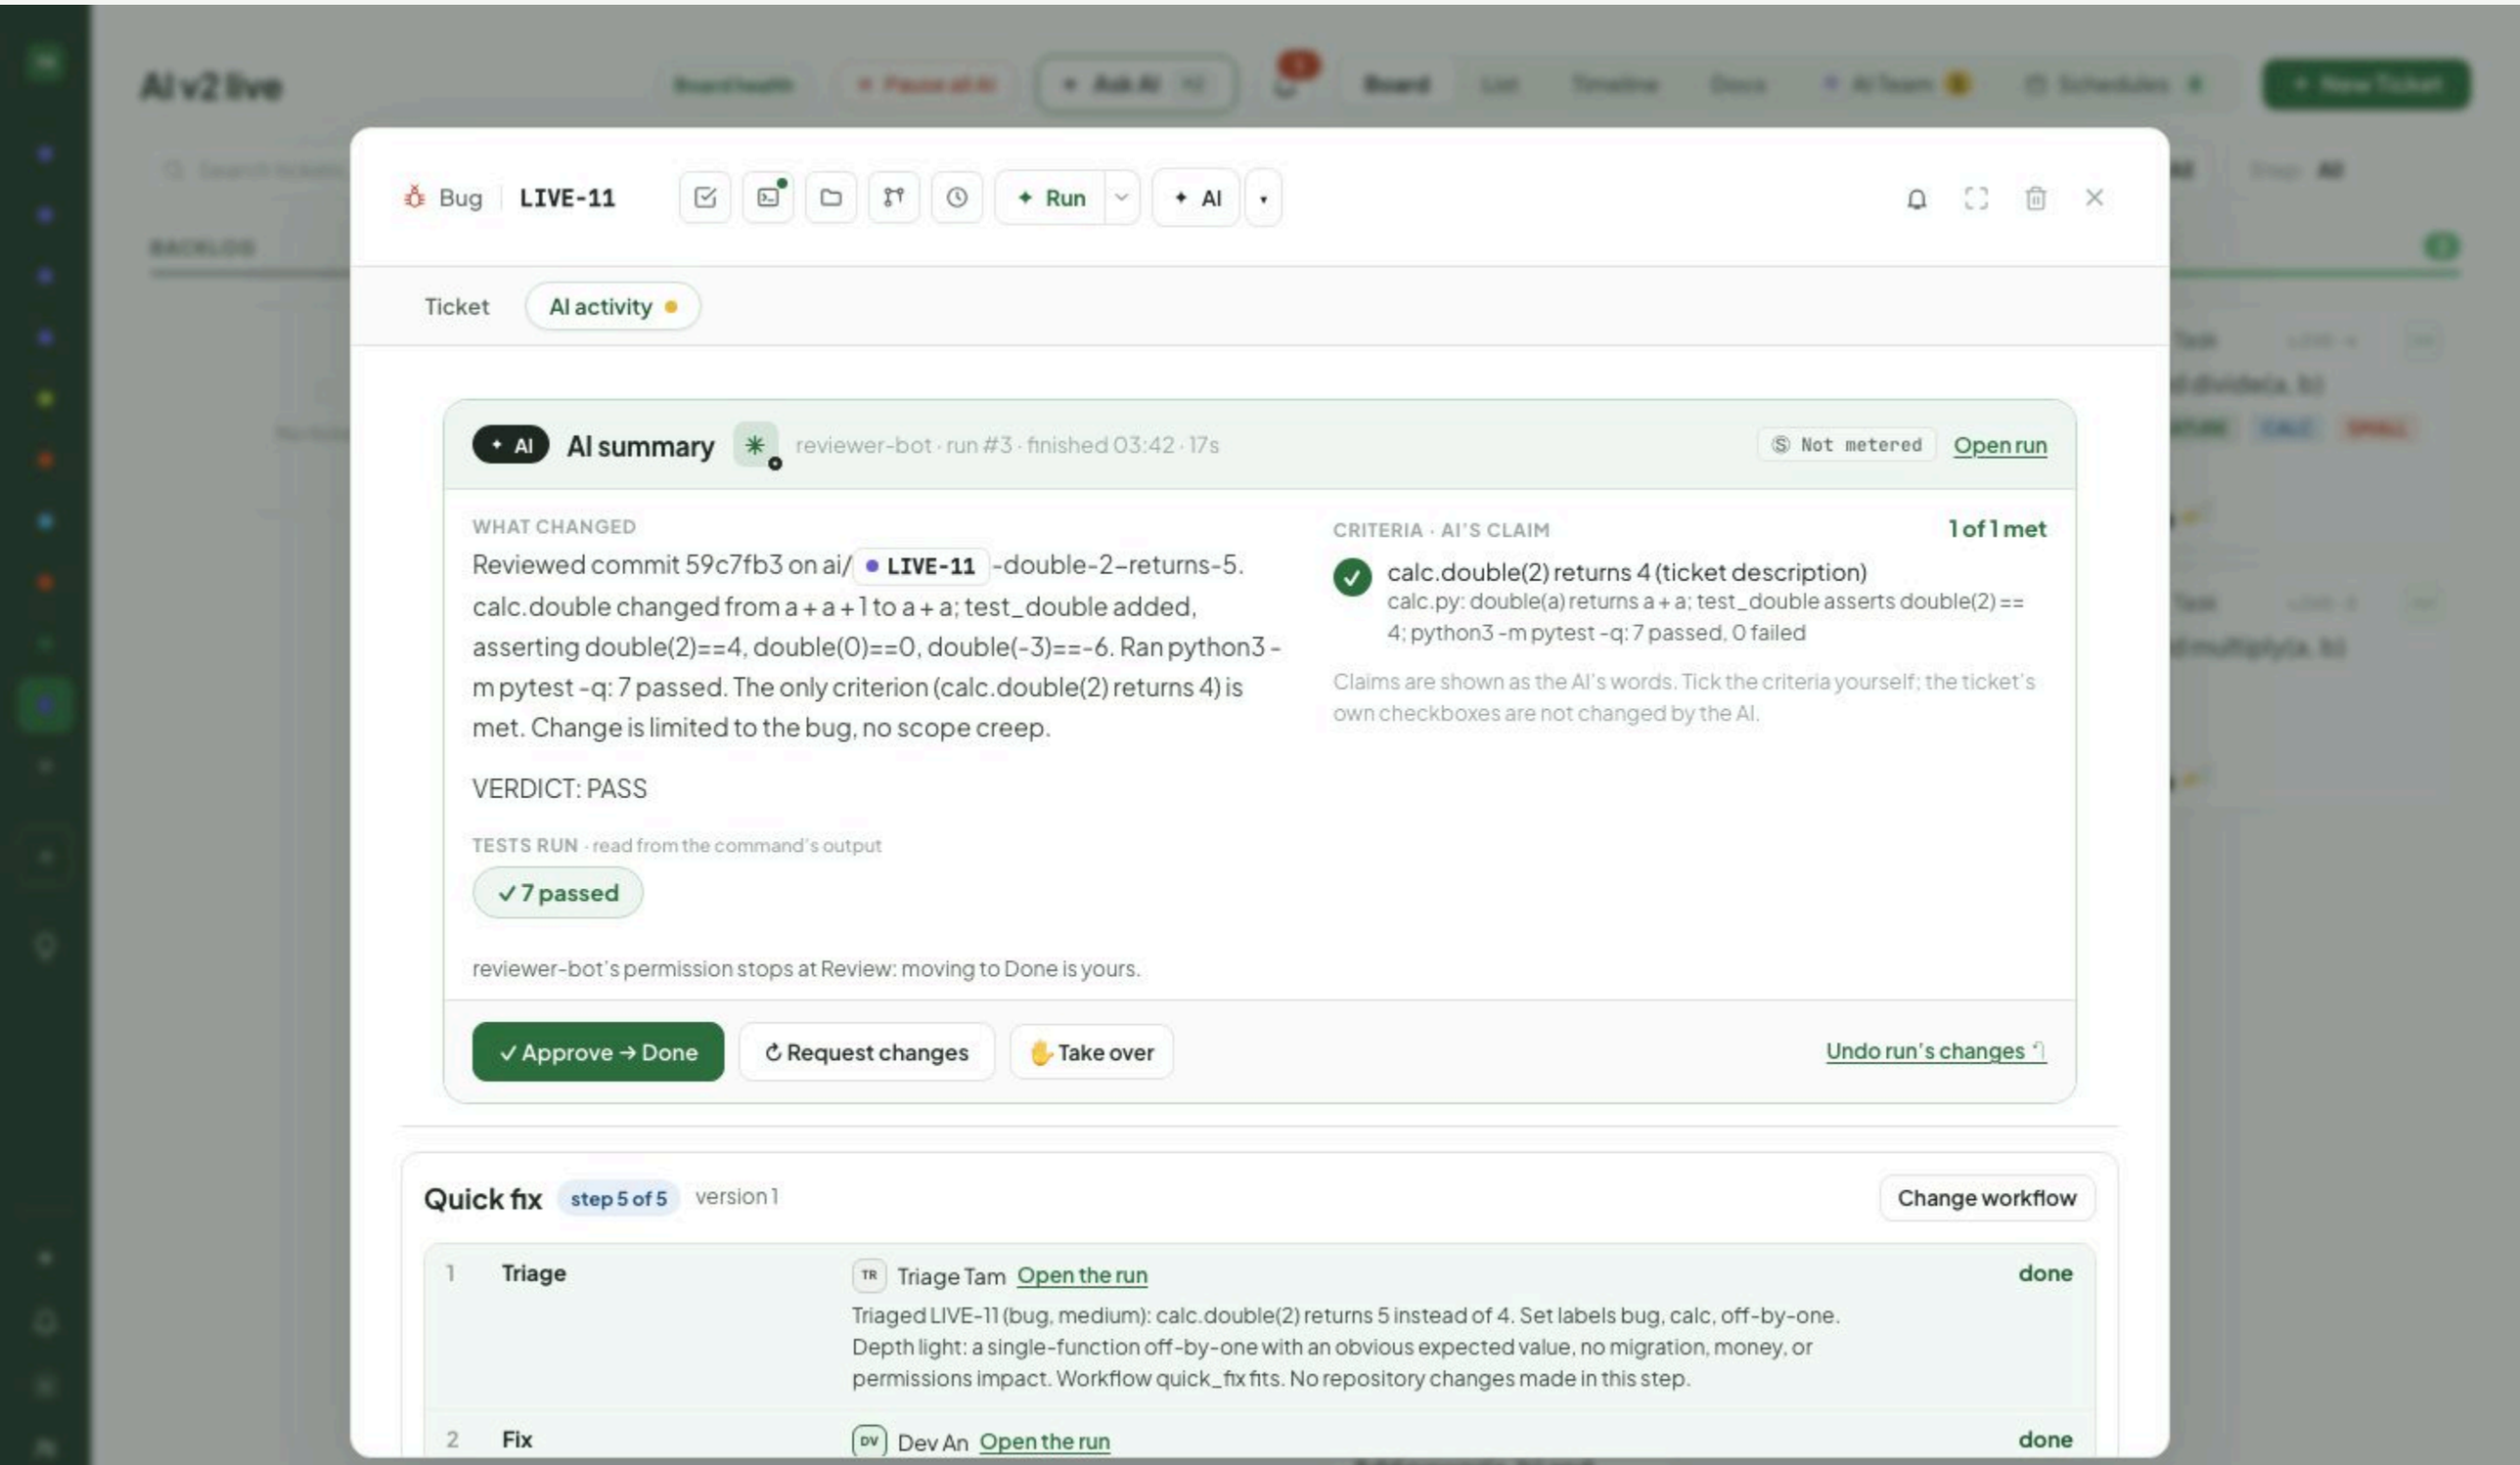

A project the AI team worked on

- Every ticket here was done by AI members on Claude Code (Sonnet and Haiku), each in its own git worktree.
- The filter bar now reads workflows: which step a ticket is at, and what waits for you.

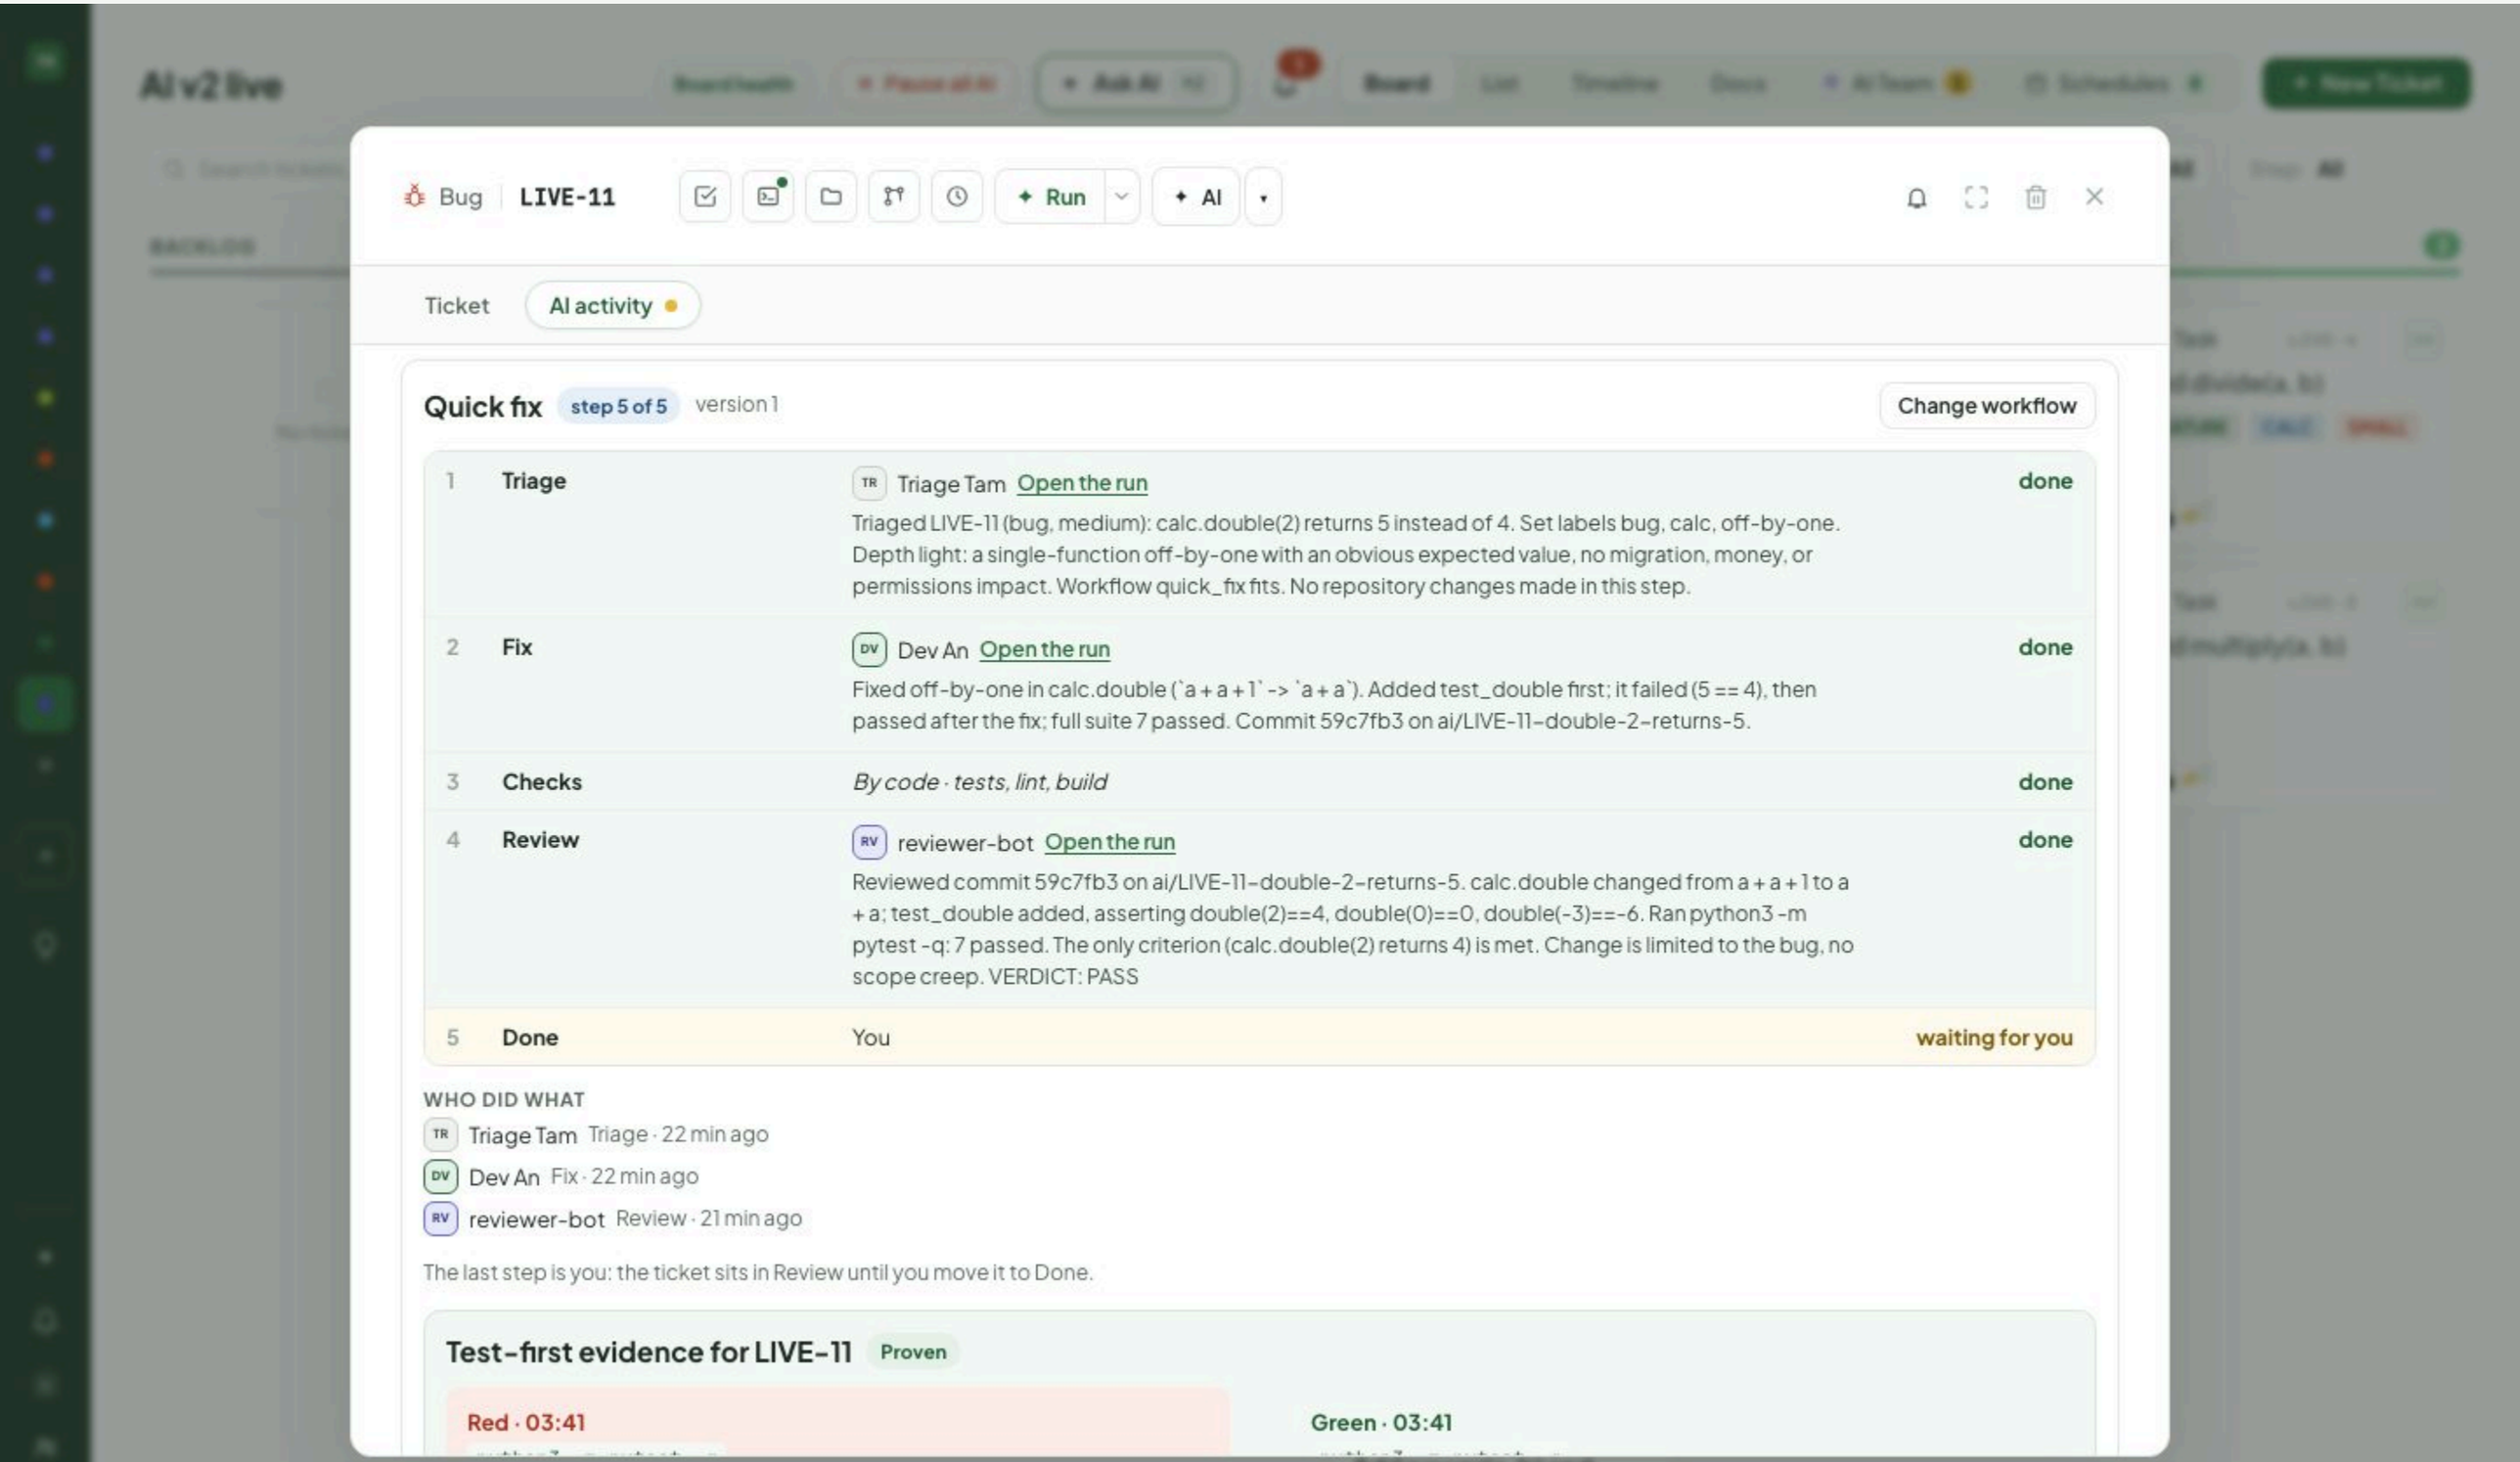

A bug fixed through the Quick fix workflow

- Triage (Haiku) sorted it, Dev (Sonnet) fixed it test-first, Checks ran the tests by code, Reviewer passed it.
- The reviewer read the diff and ran the tests itself: “7 passed”. Done stays a person’s move.

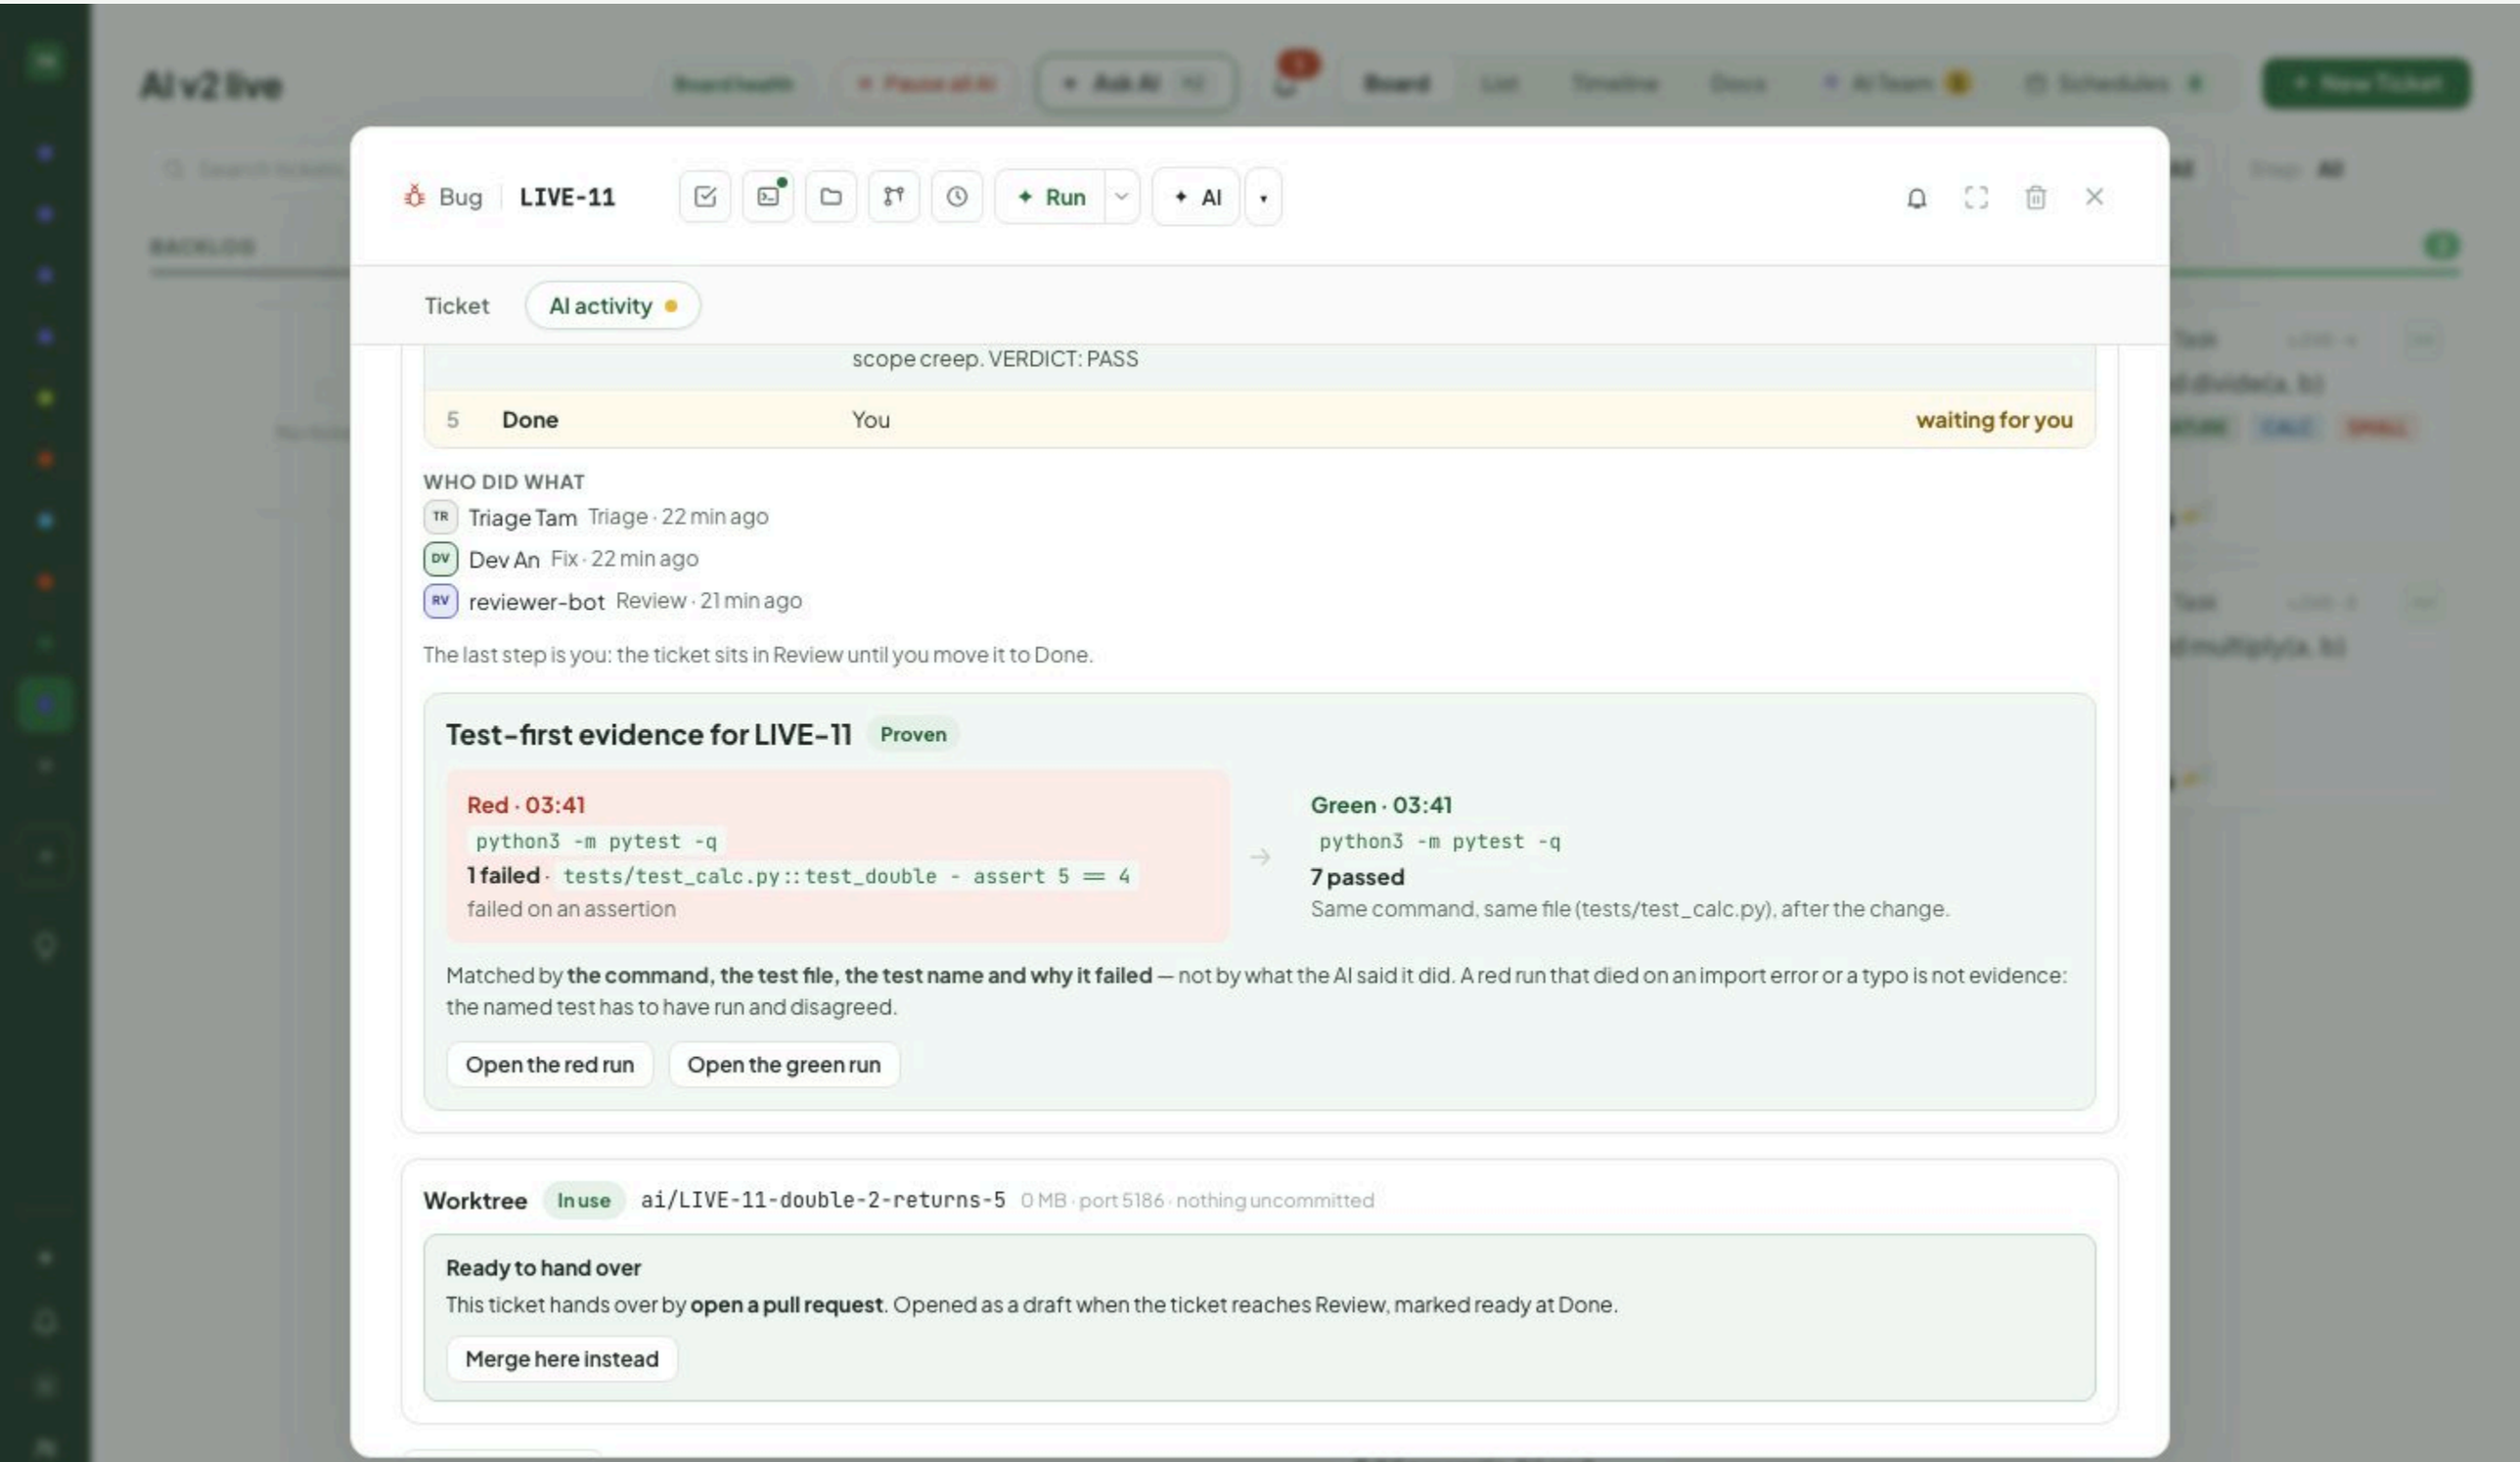

Who held the ticket, step by step

- Each step names the AI that held it and links its run; the history is never overwritten.
- Triage set the labels and a light review depth; Checks ran the project's test command in the worktree.

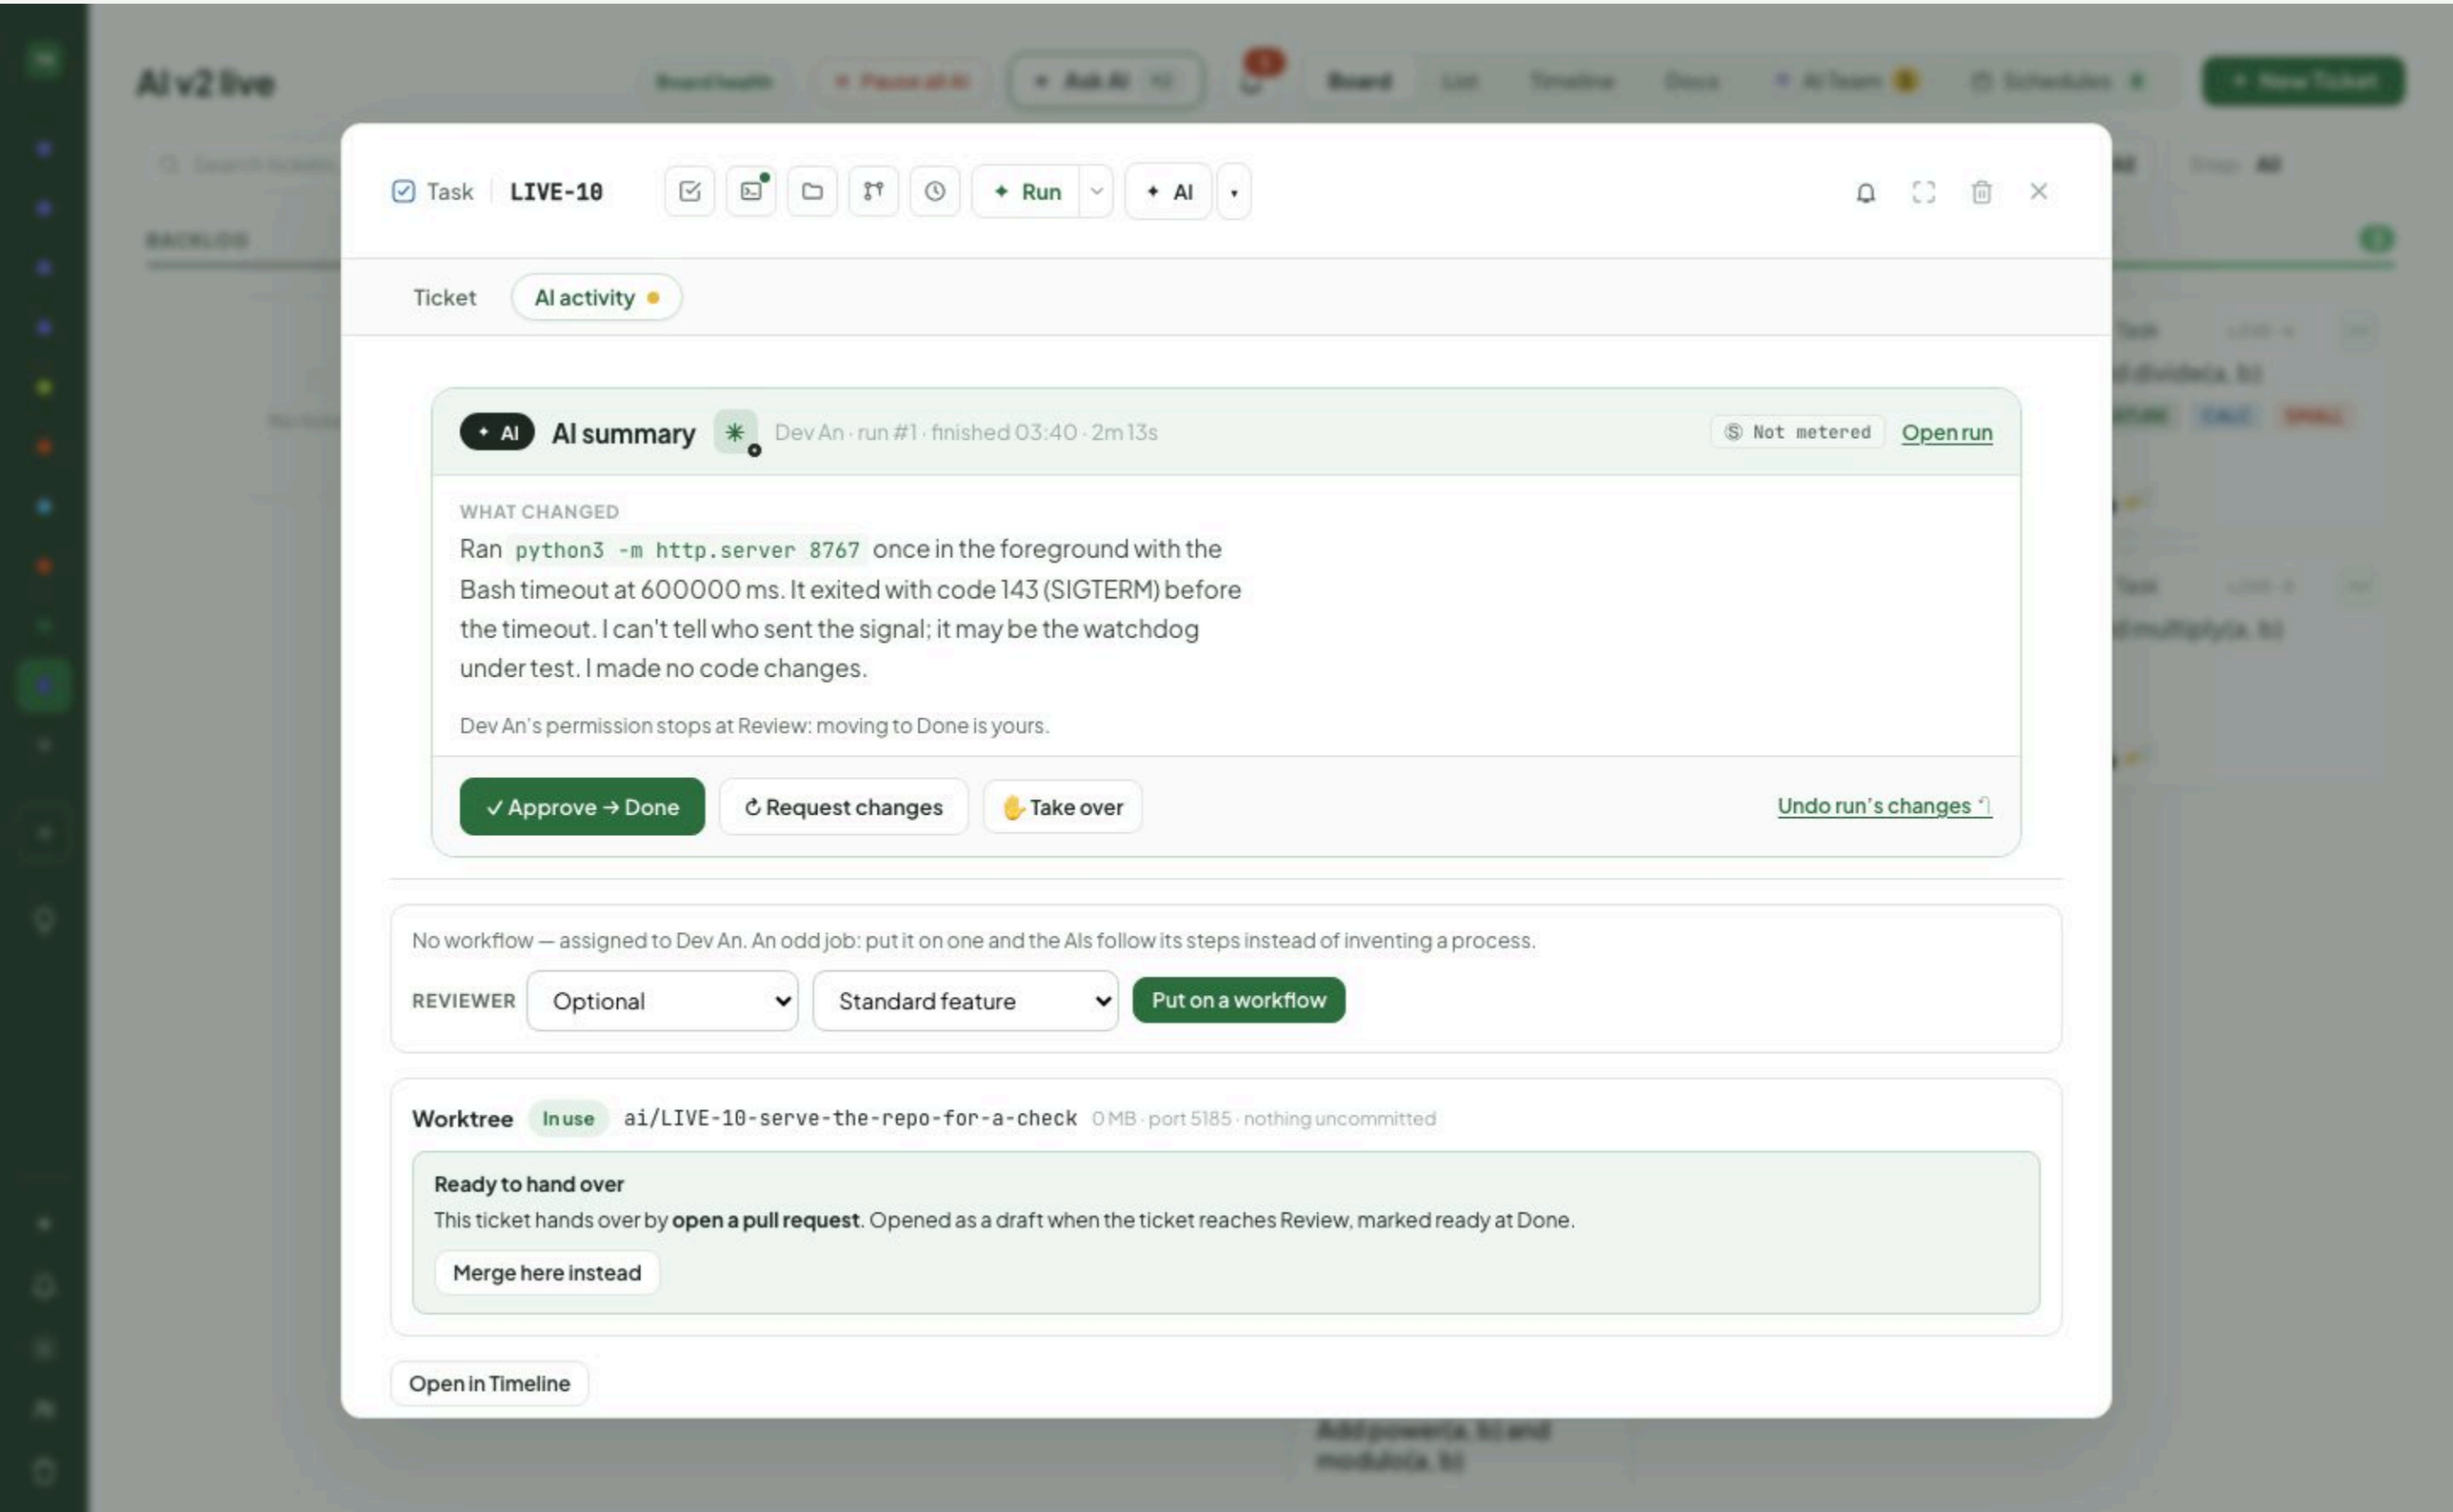

Proof that the test went red first

- Read from the runs' own command output: "assert 5 == 4" failed, then the same command passed.
- A run that died on an import error never ran the test, so it would not count.

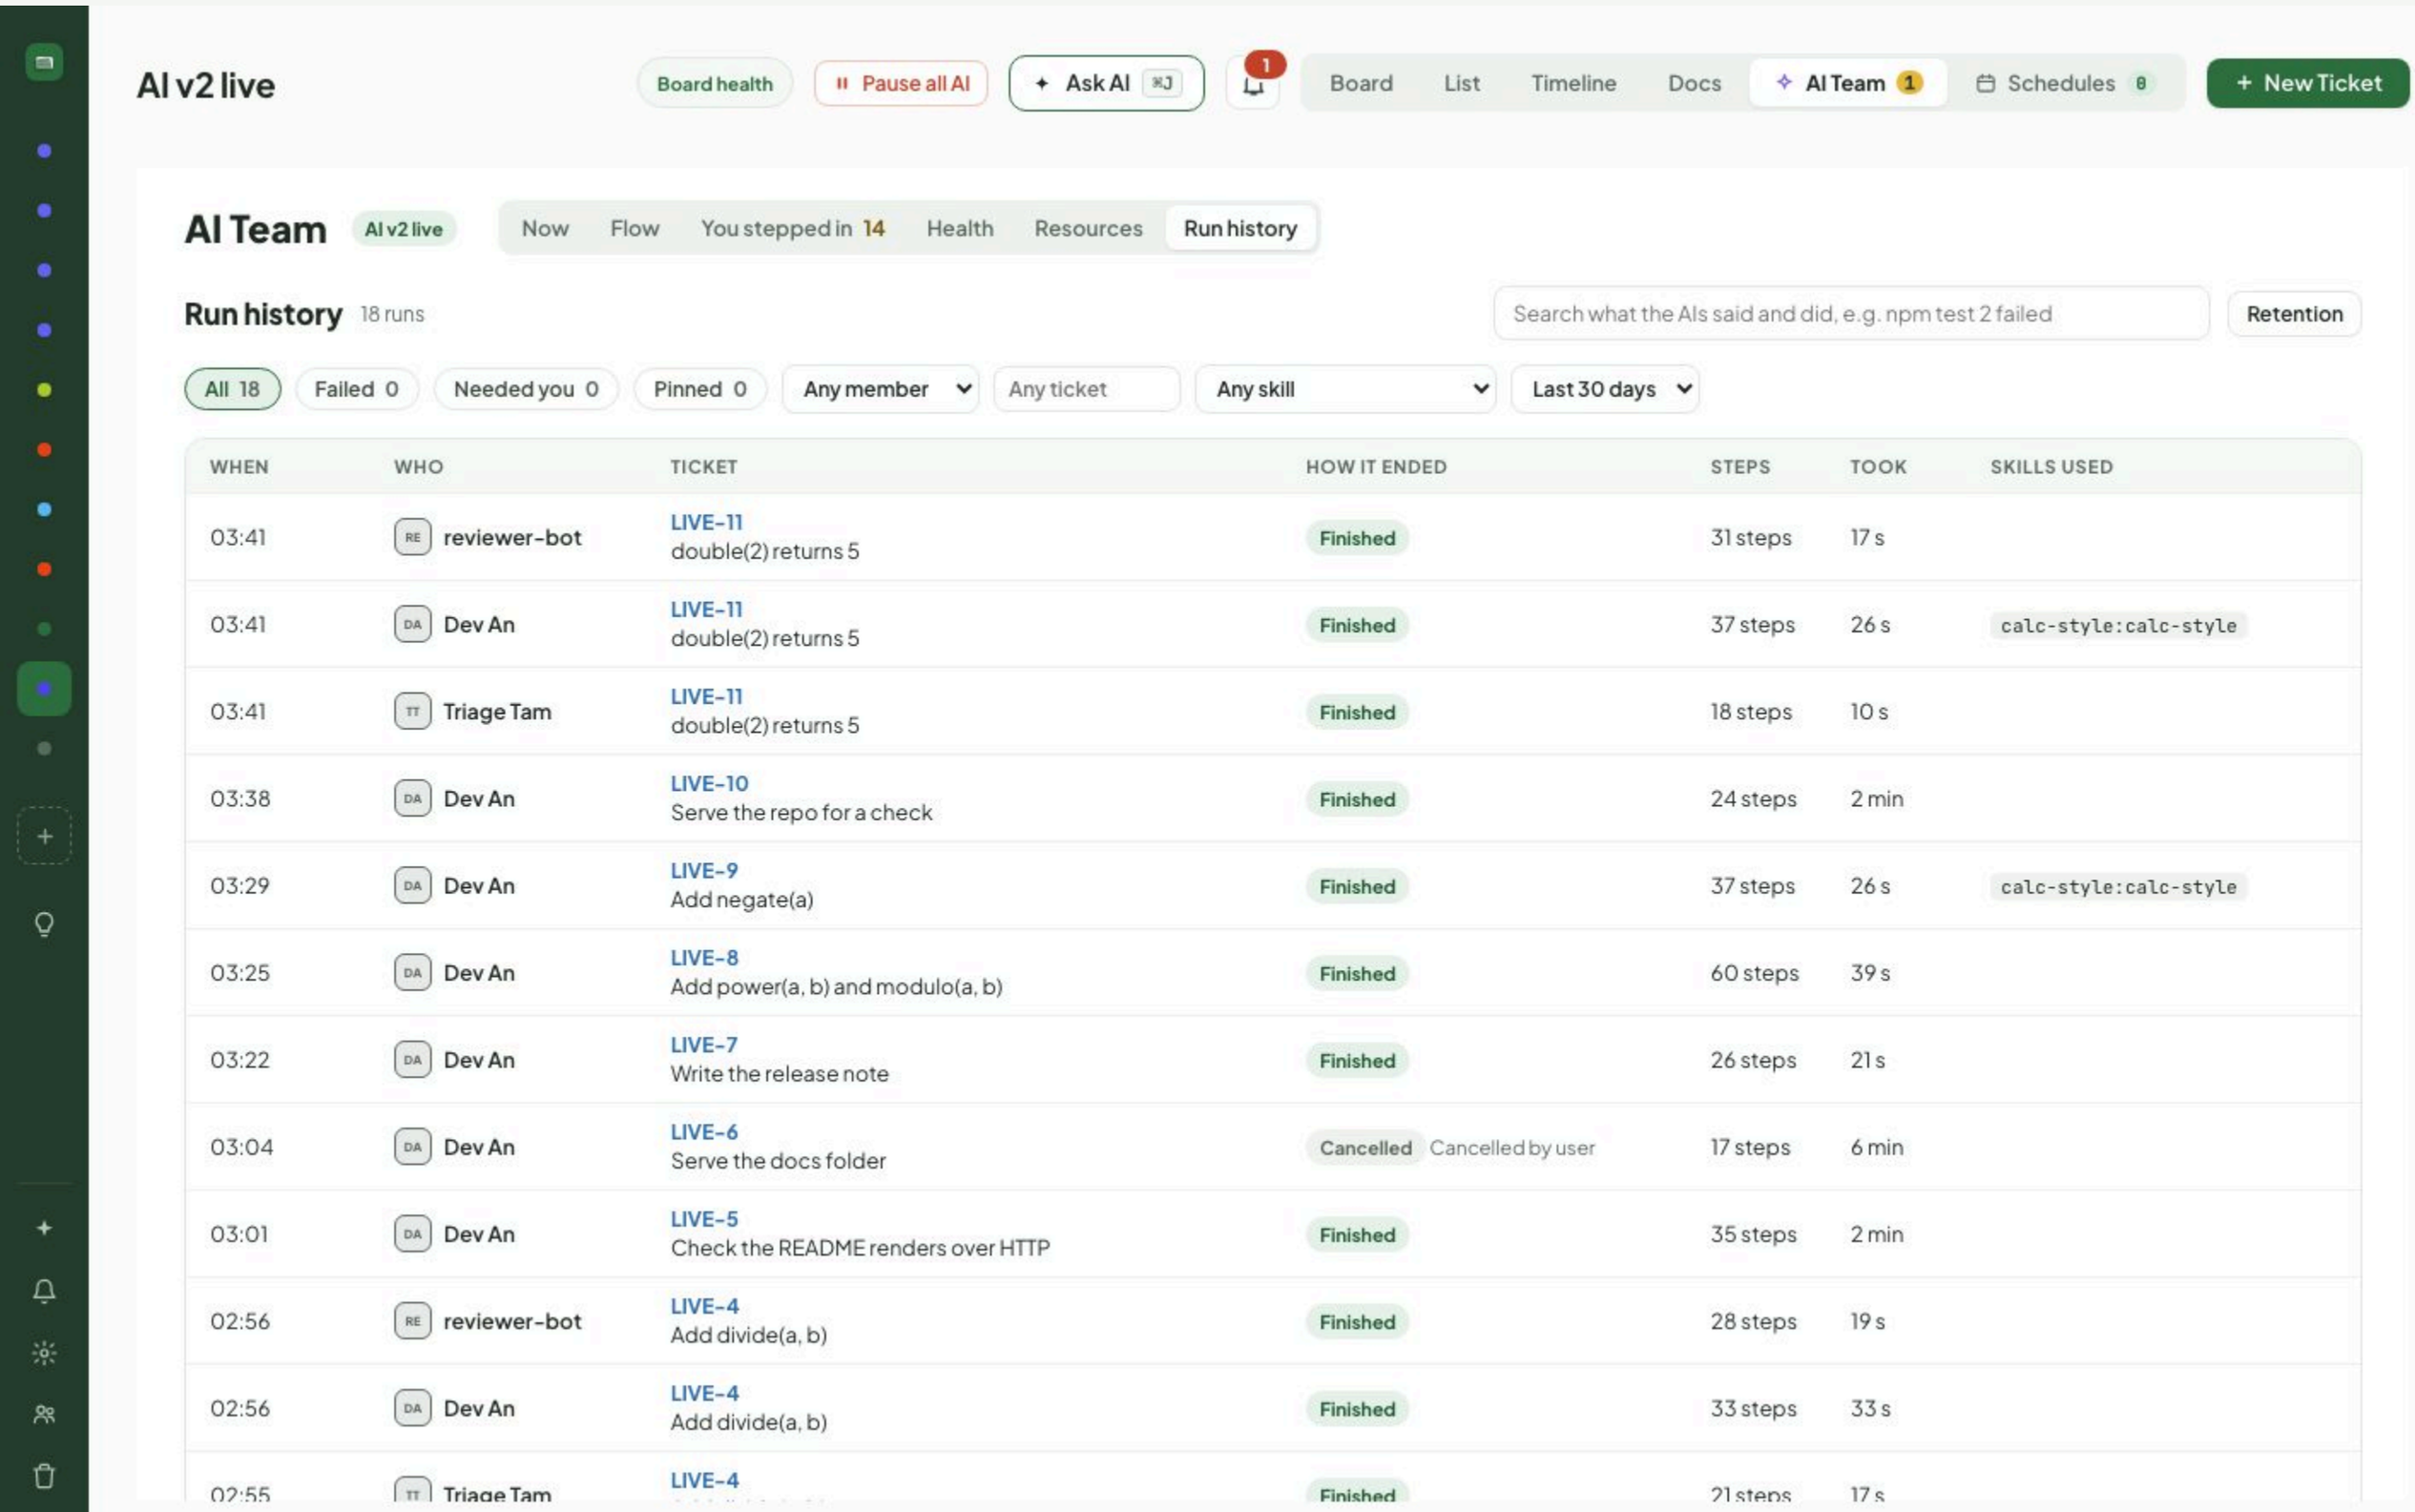

An AI that hung on a foreground server

- The run printed nothing for 90 s with python3 -m http.server open: the board diagnosed it by code.
- “Stop that command” stopped only the server; the run carried on and finished, and a lesson was proposed.

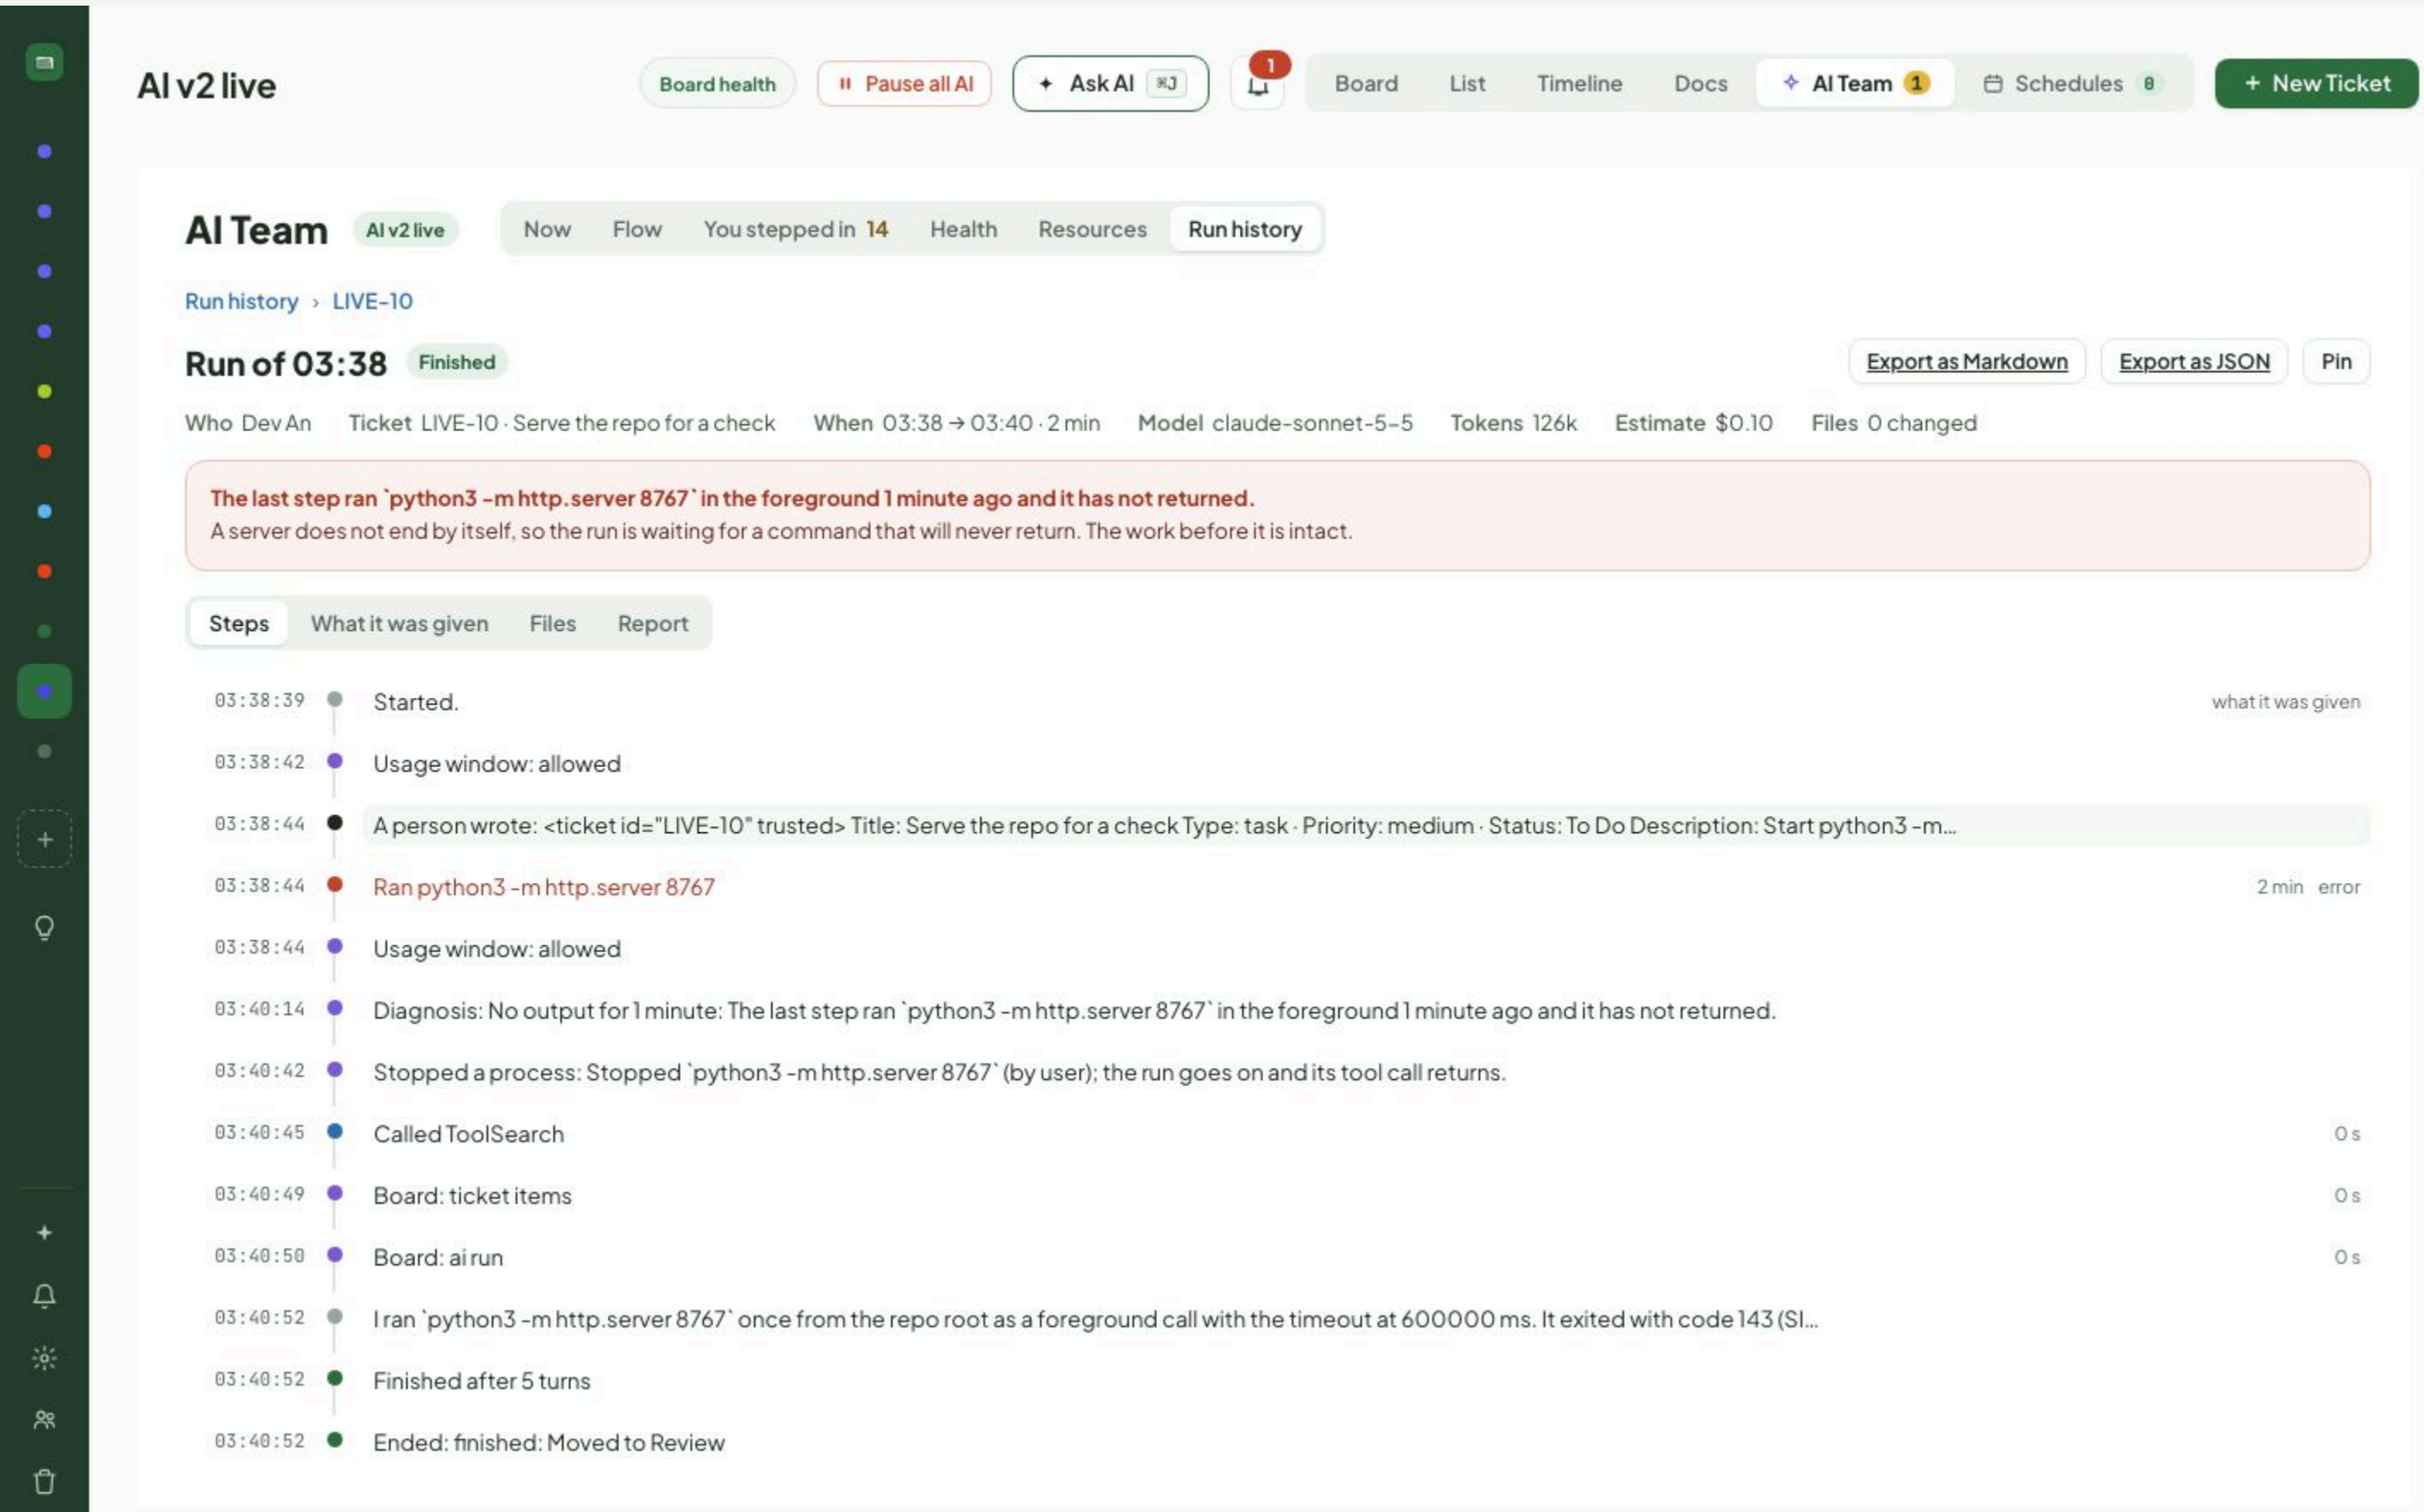

Every run, kept by the board

- The board keeps its own transcript of each run: what it sent and every line the CLI printed, secrets masked.
- Search reads the transcripts (FTS5): a command, a file, a test name.

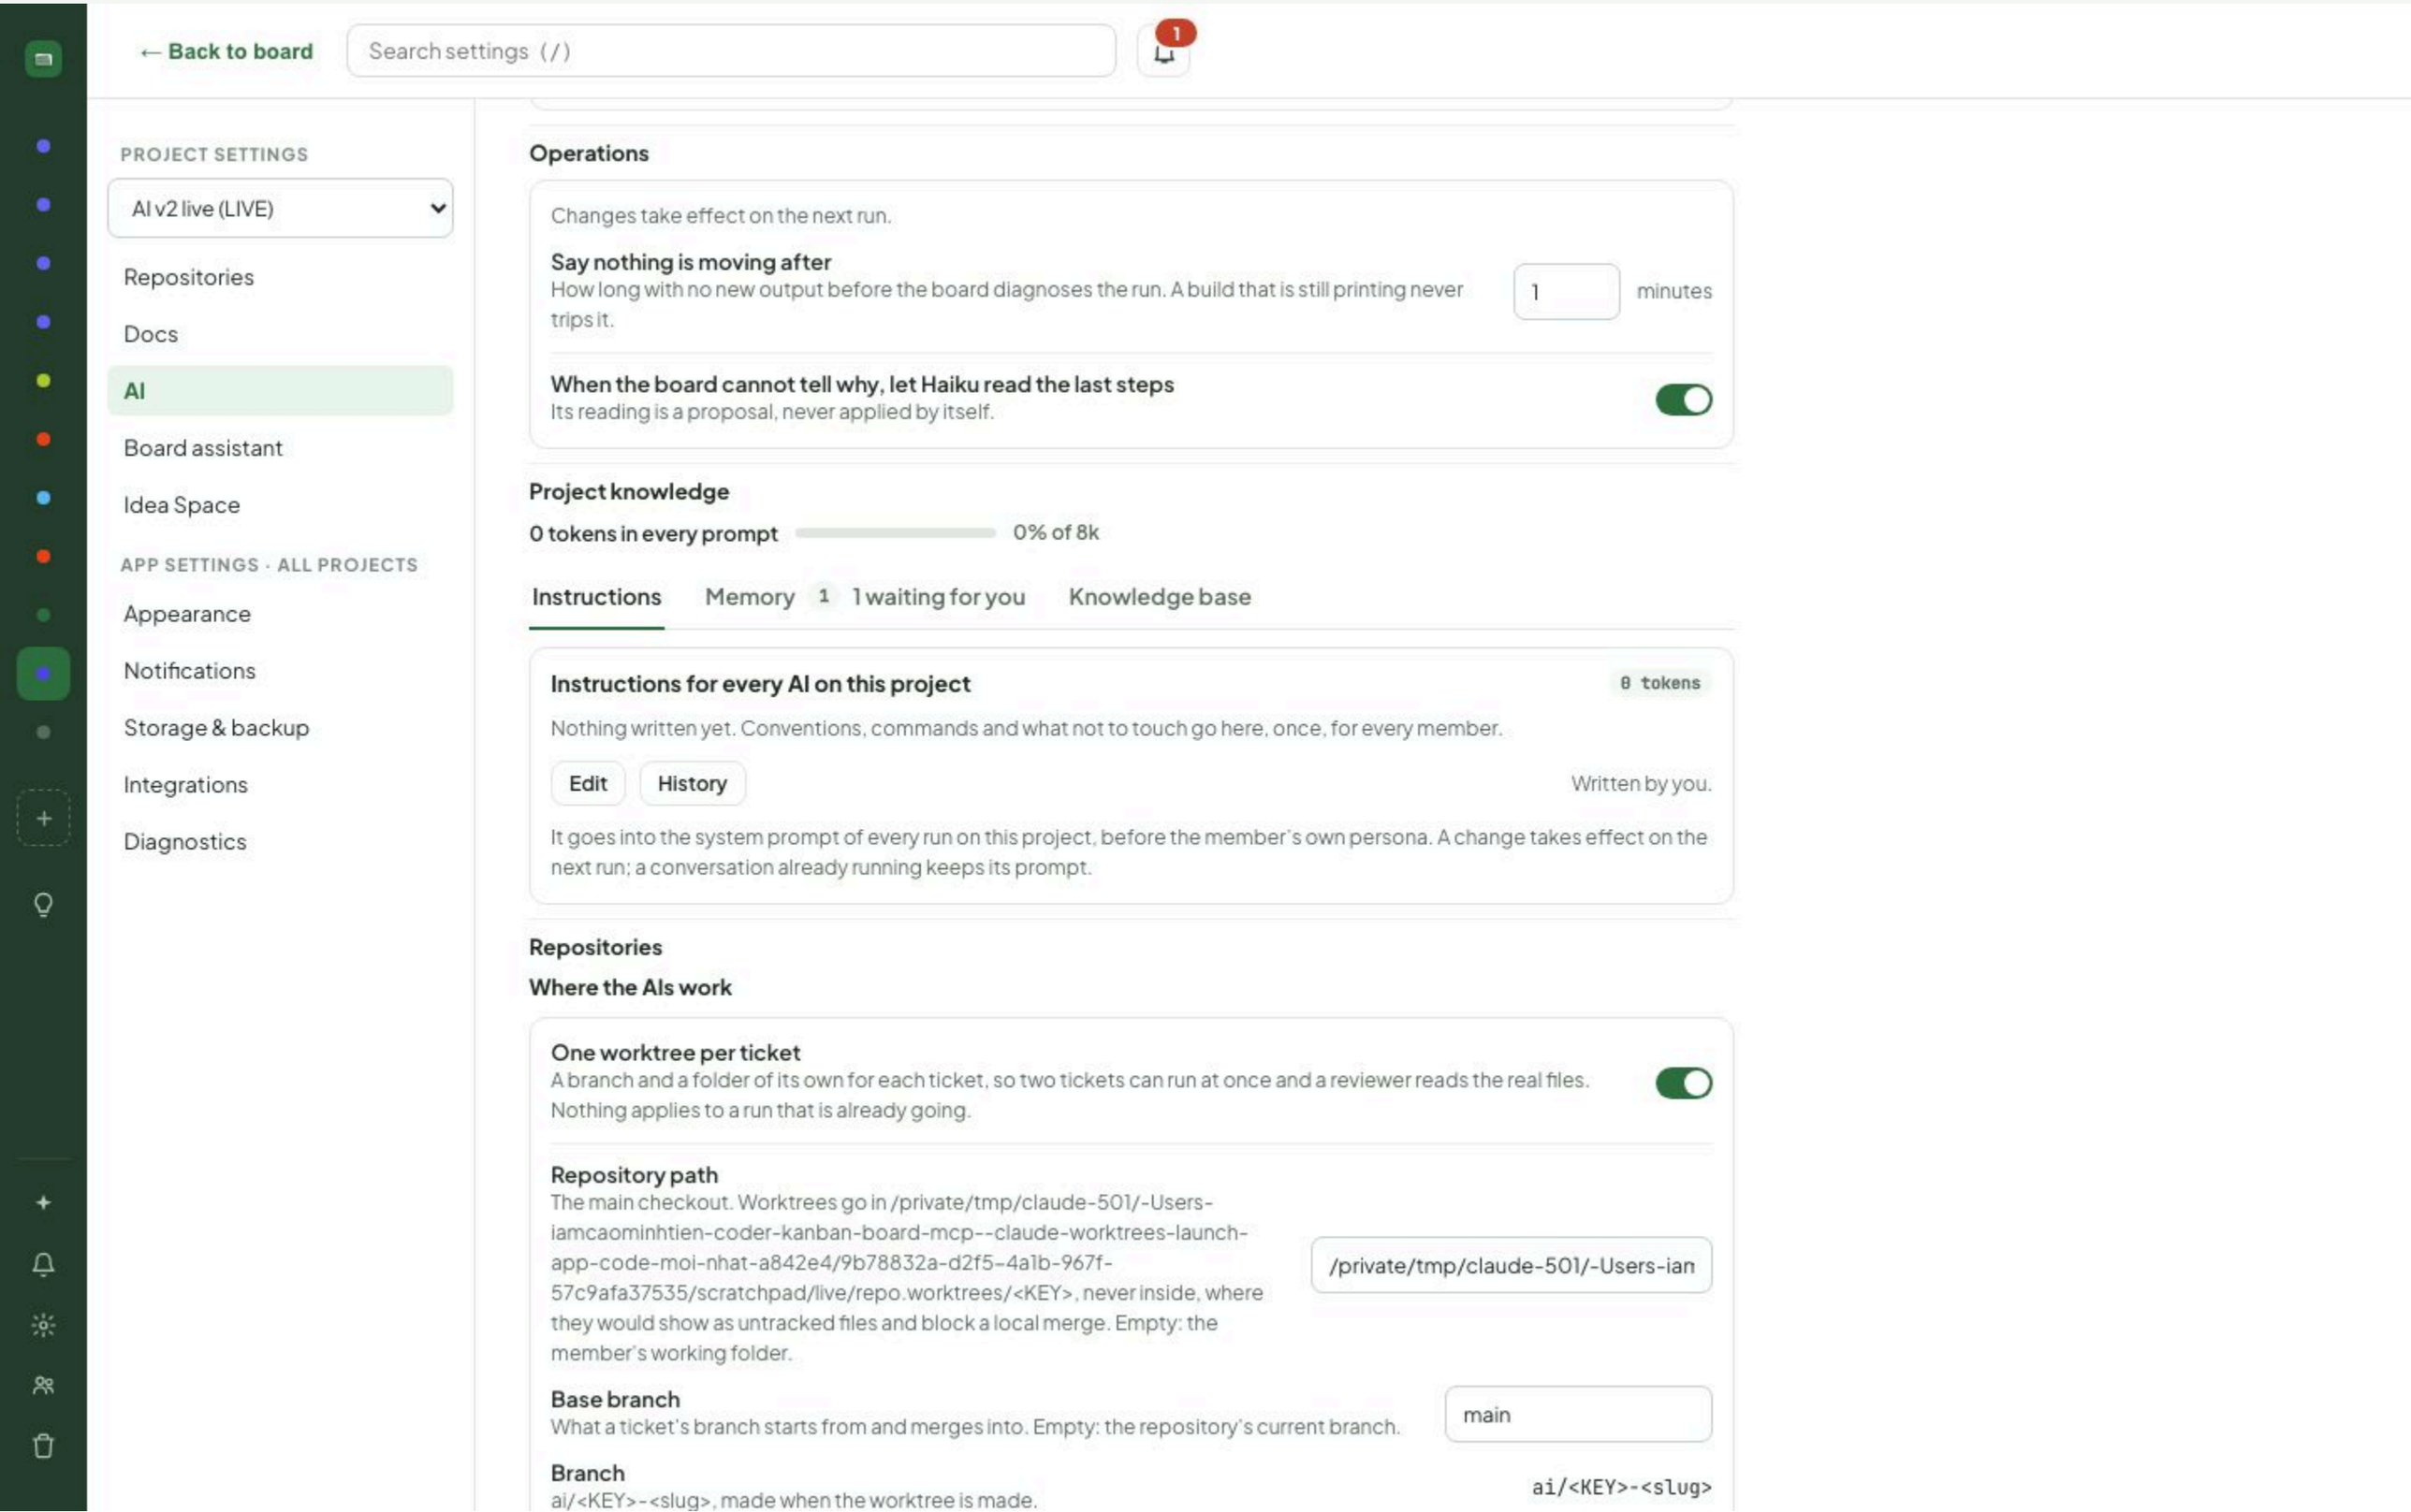

A run, step by step

- The prompt it was sent, each tool call with its output, the diagnosis and what was done about it.

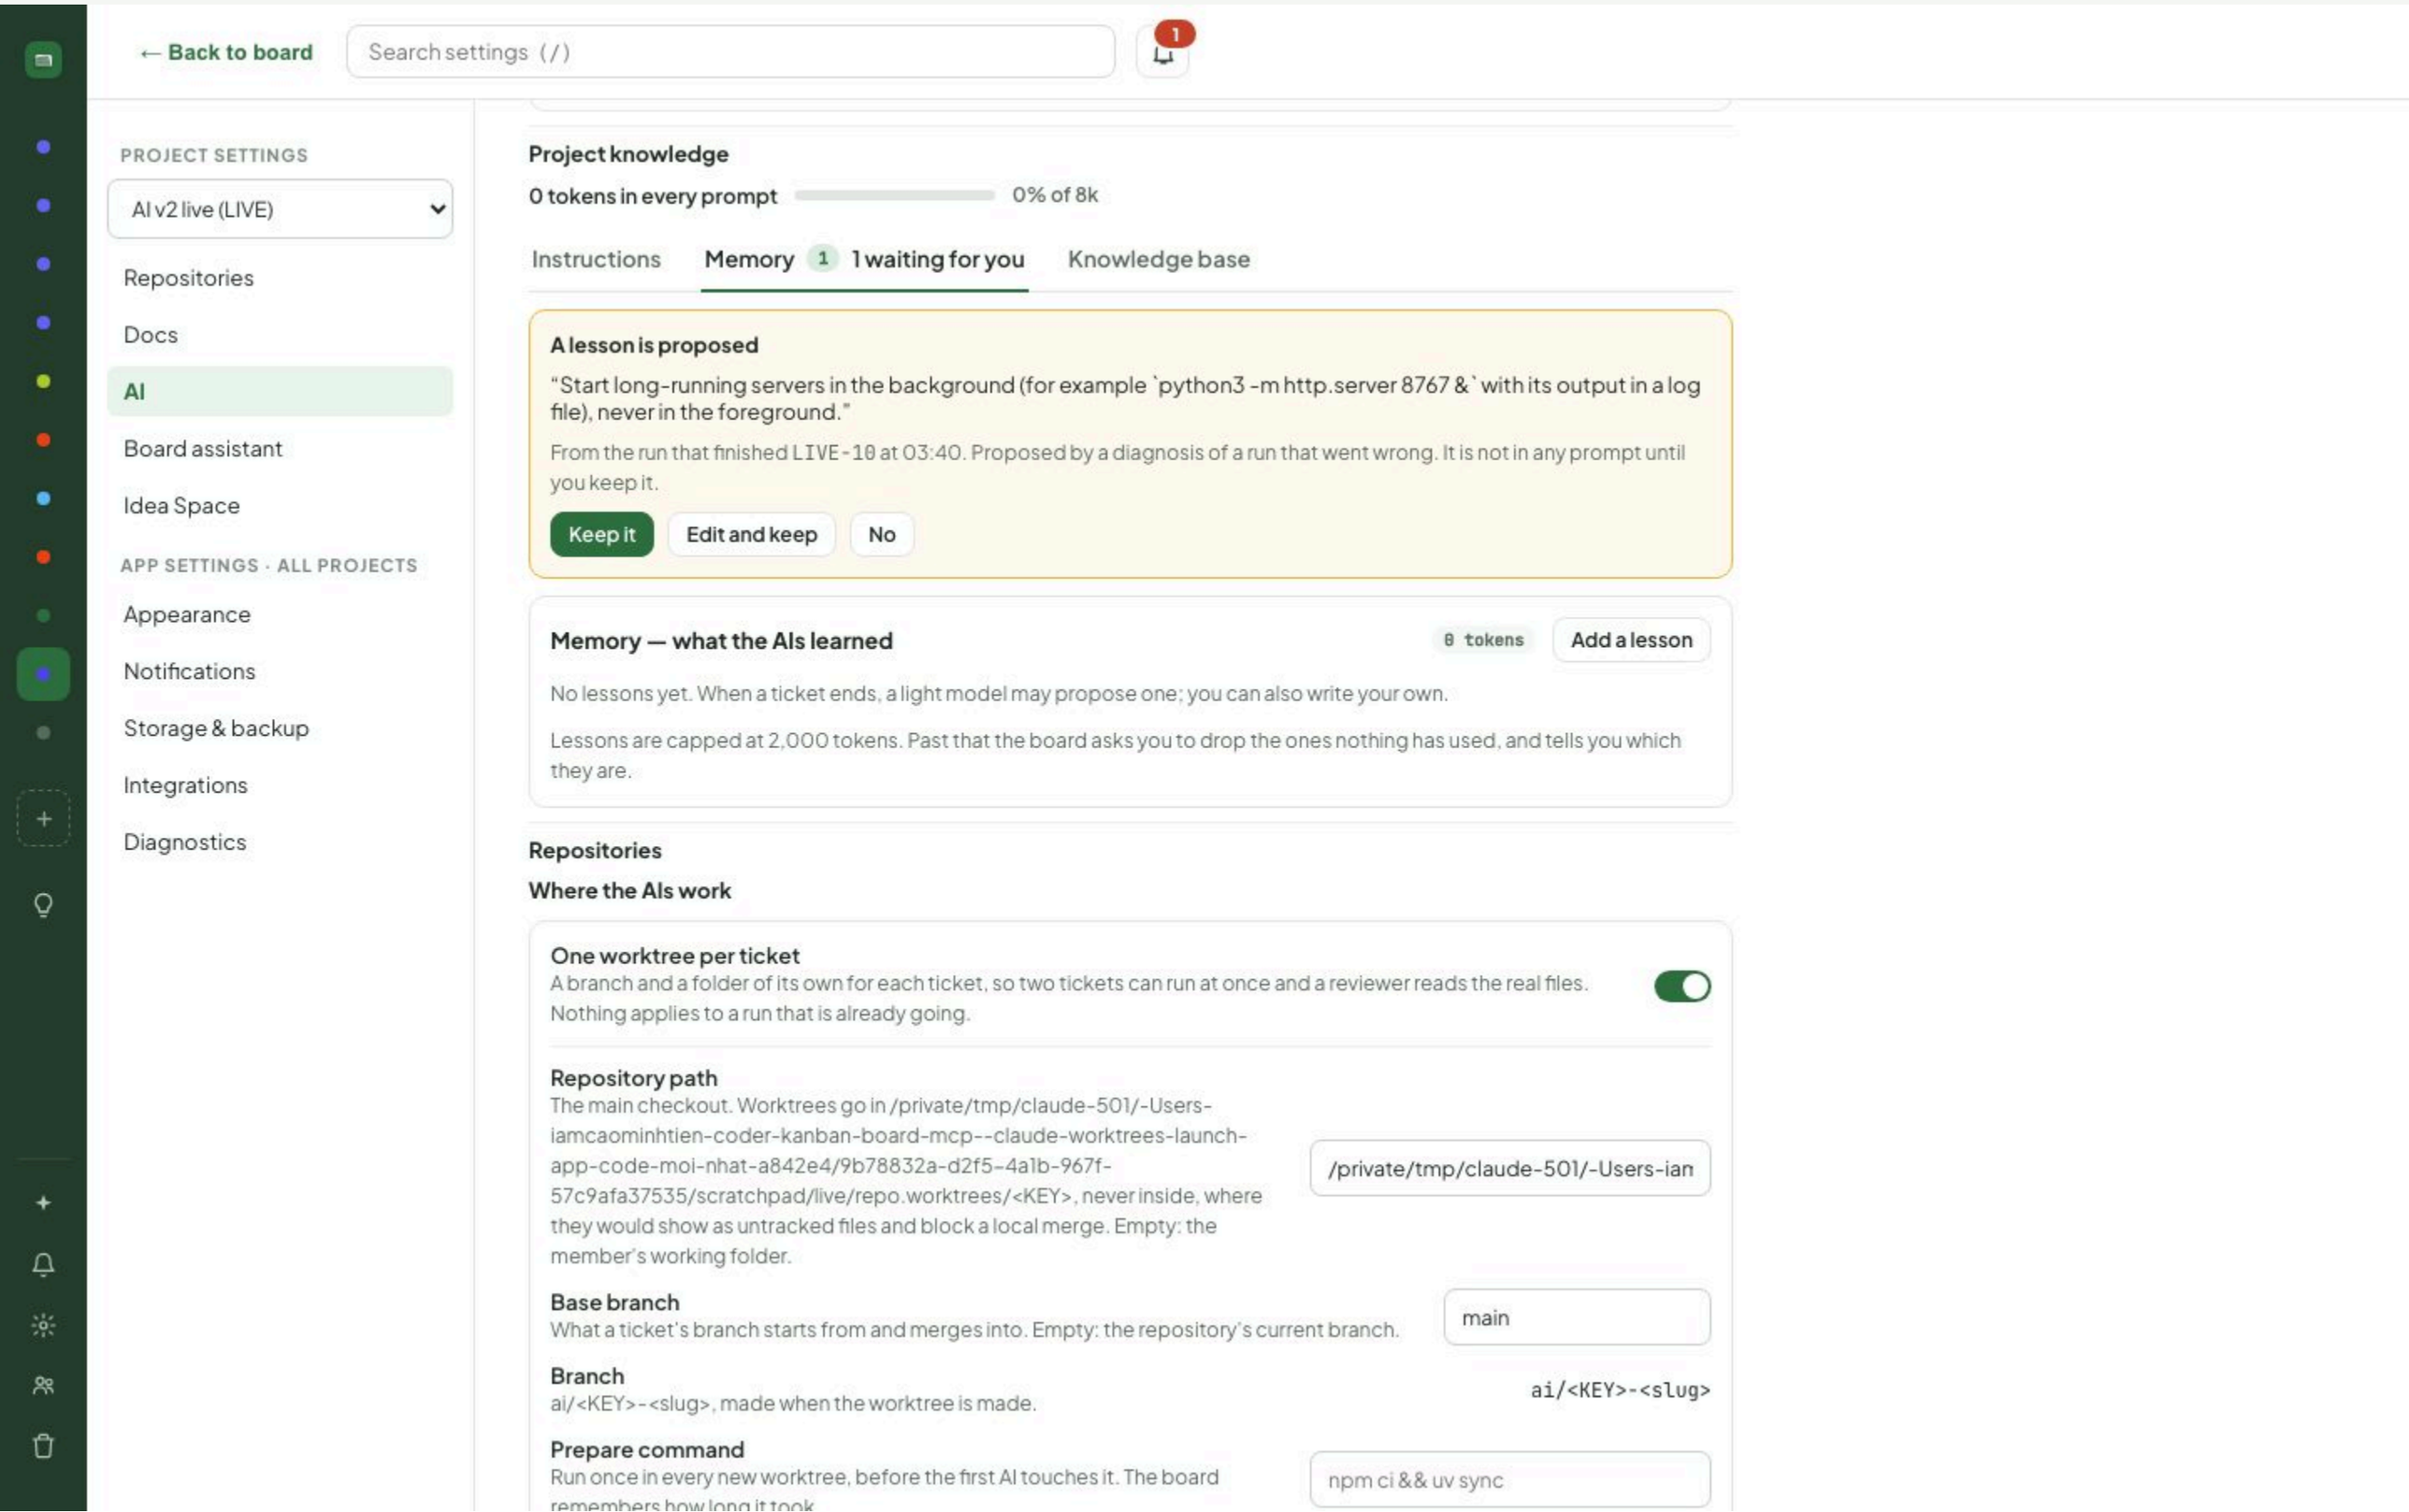

Operations, per project

- When the board says nothing is moving, and whether Haiku may read the last steps when the code cannot tell.
- Project knowledge: instructions every AI gets, and the lessons its AIs learned.

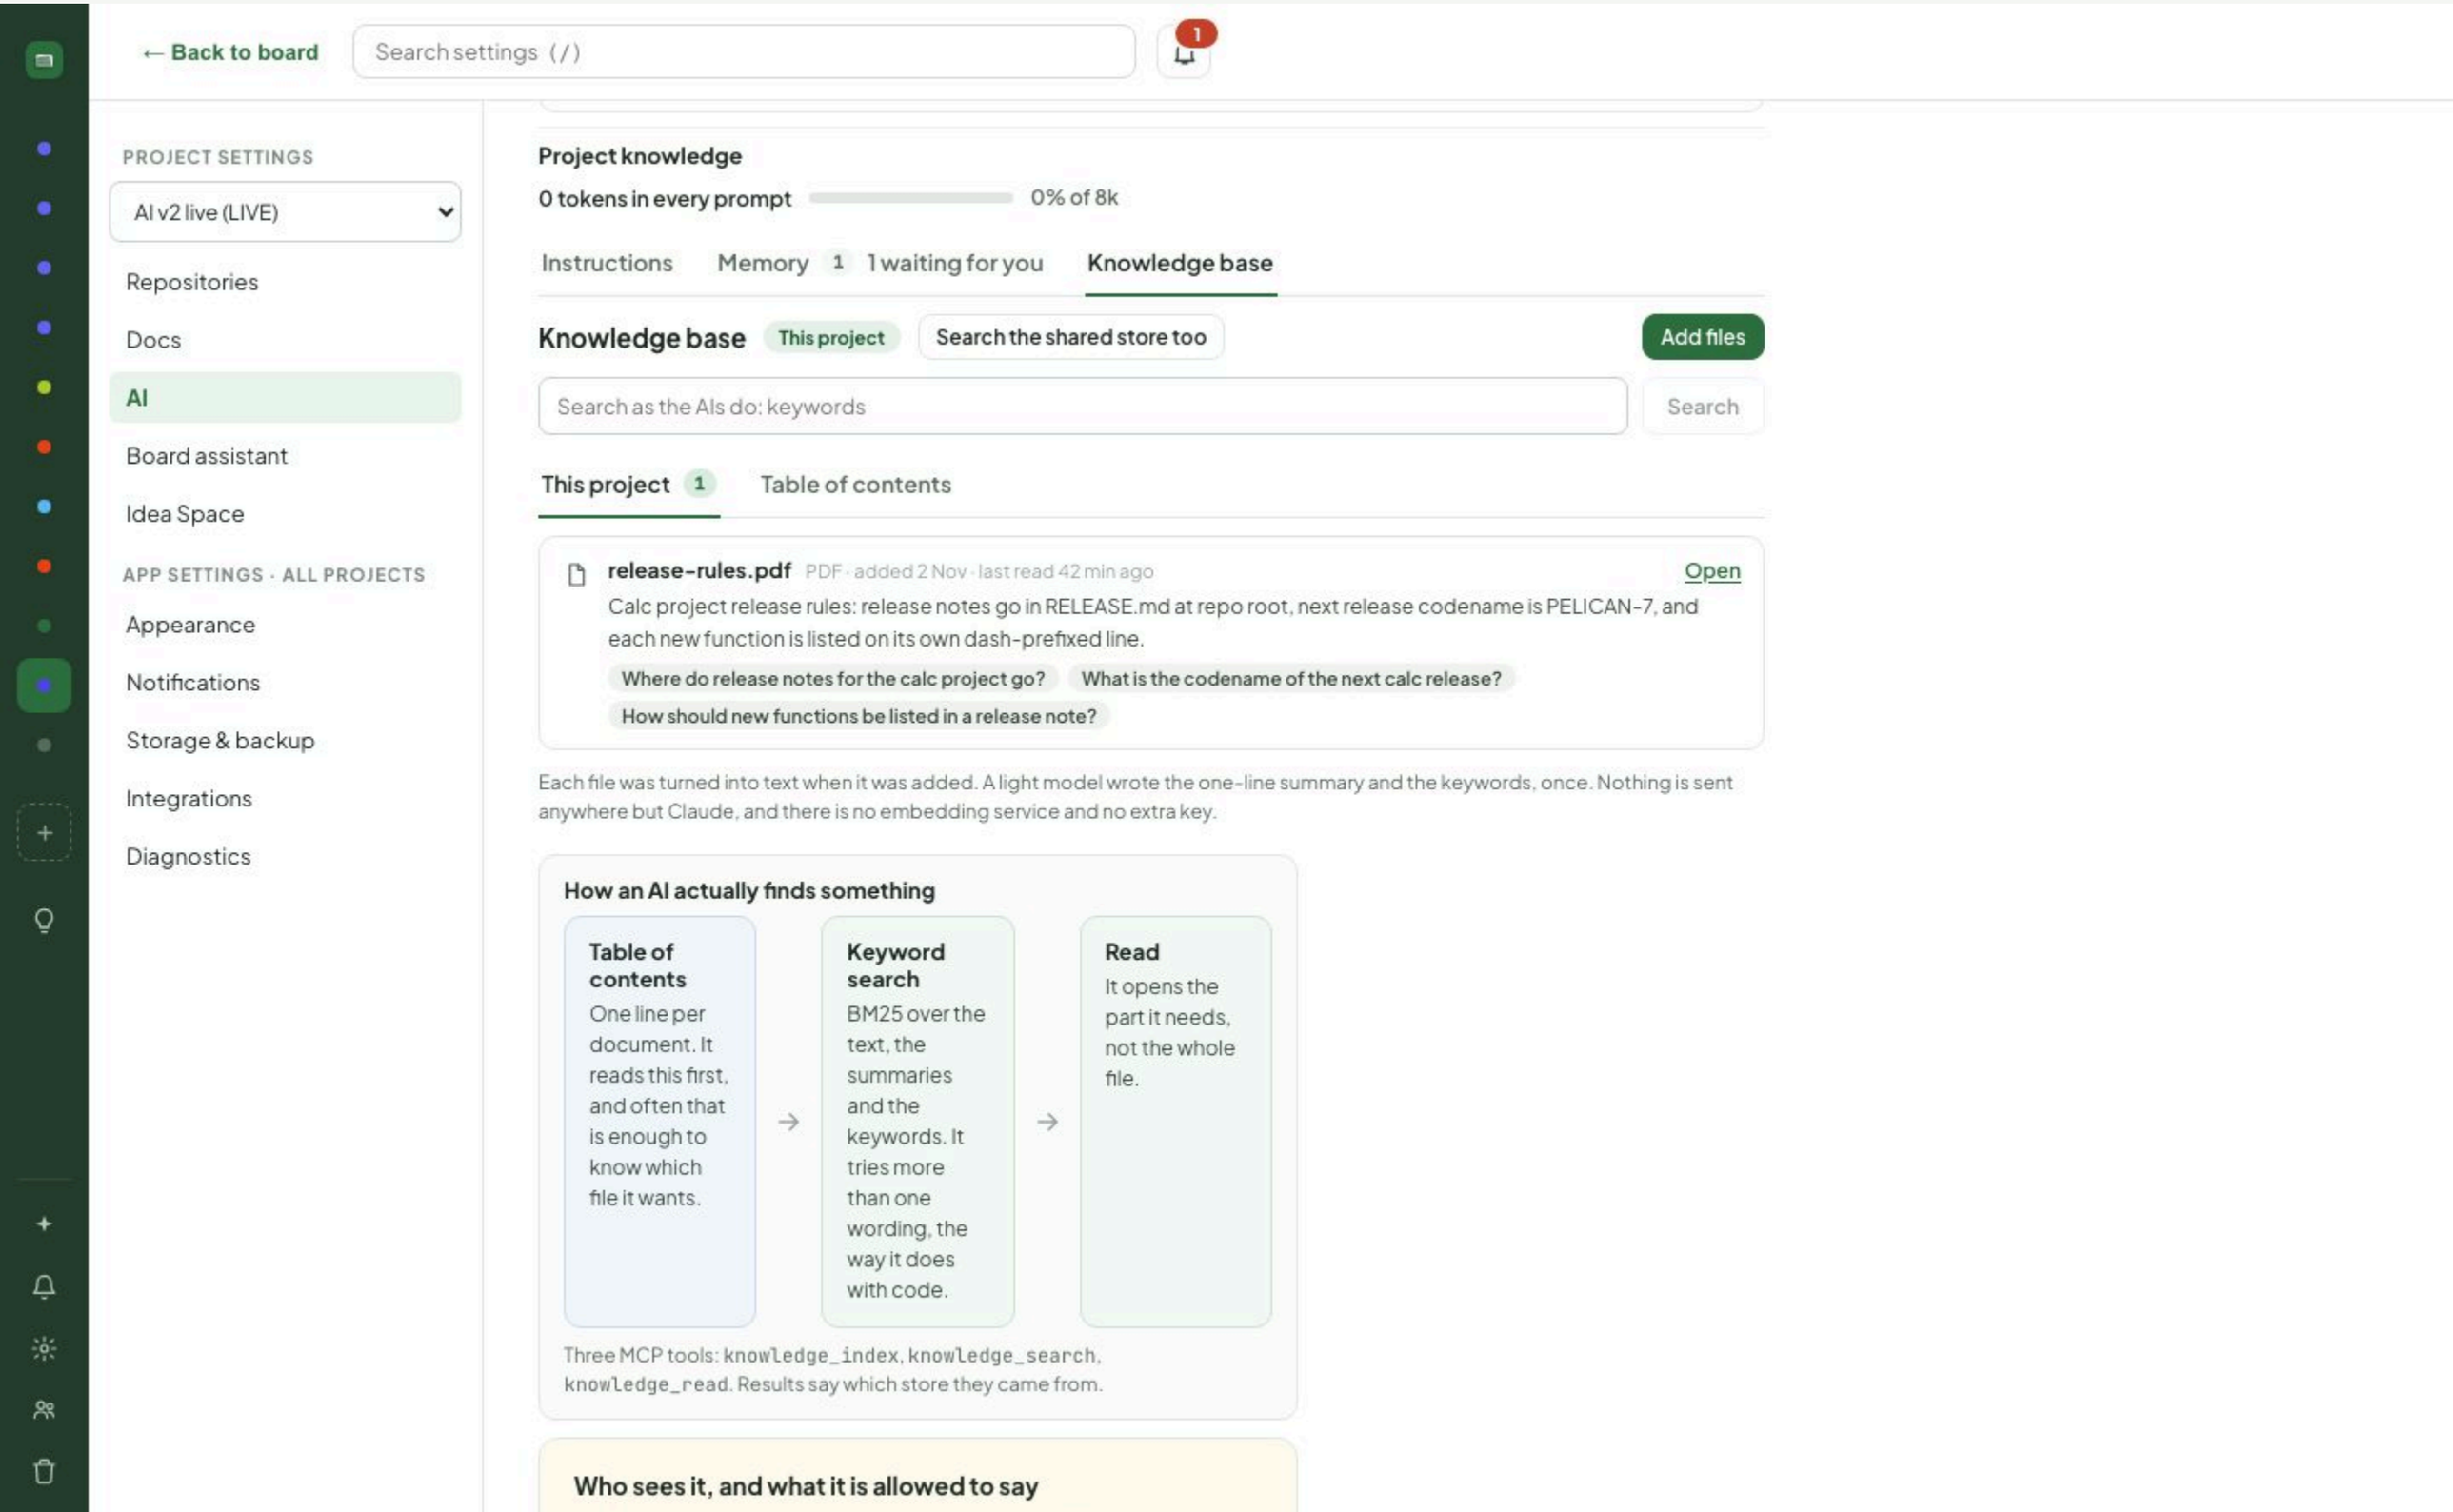

A lesson proposed by a diagnosis

- “Start long-running servers in the background” came from the hang above; a person keeps, edits or drops it.

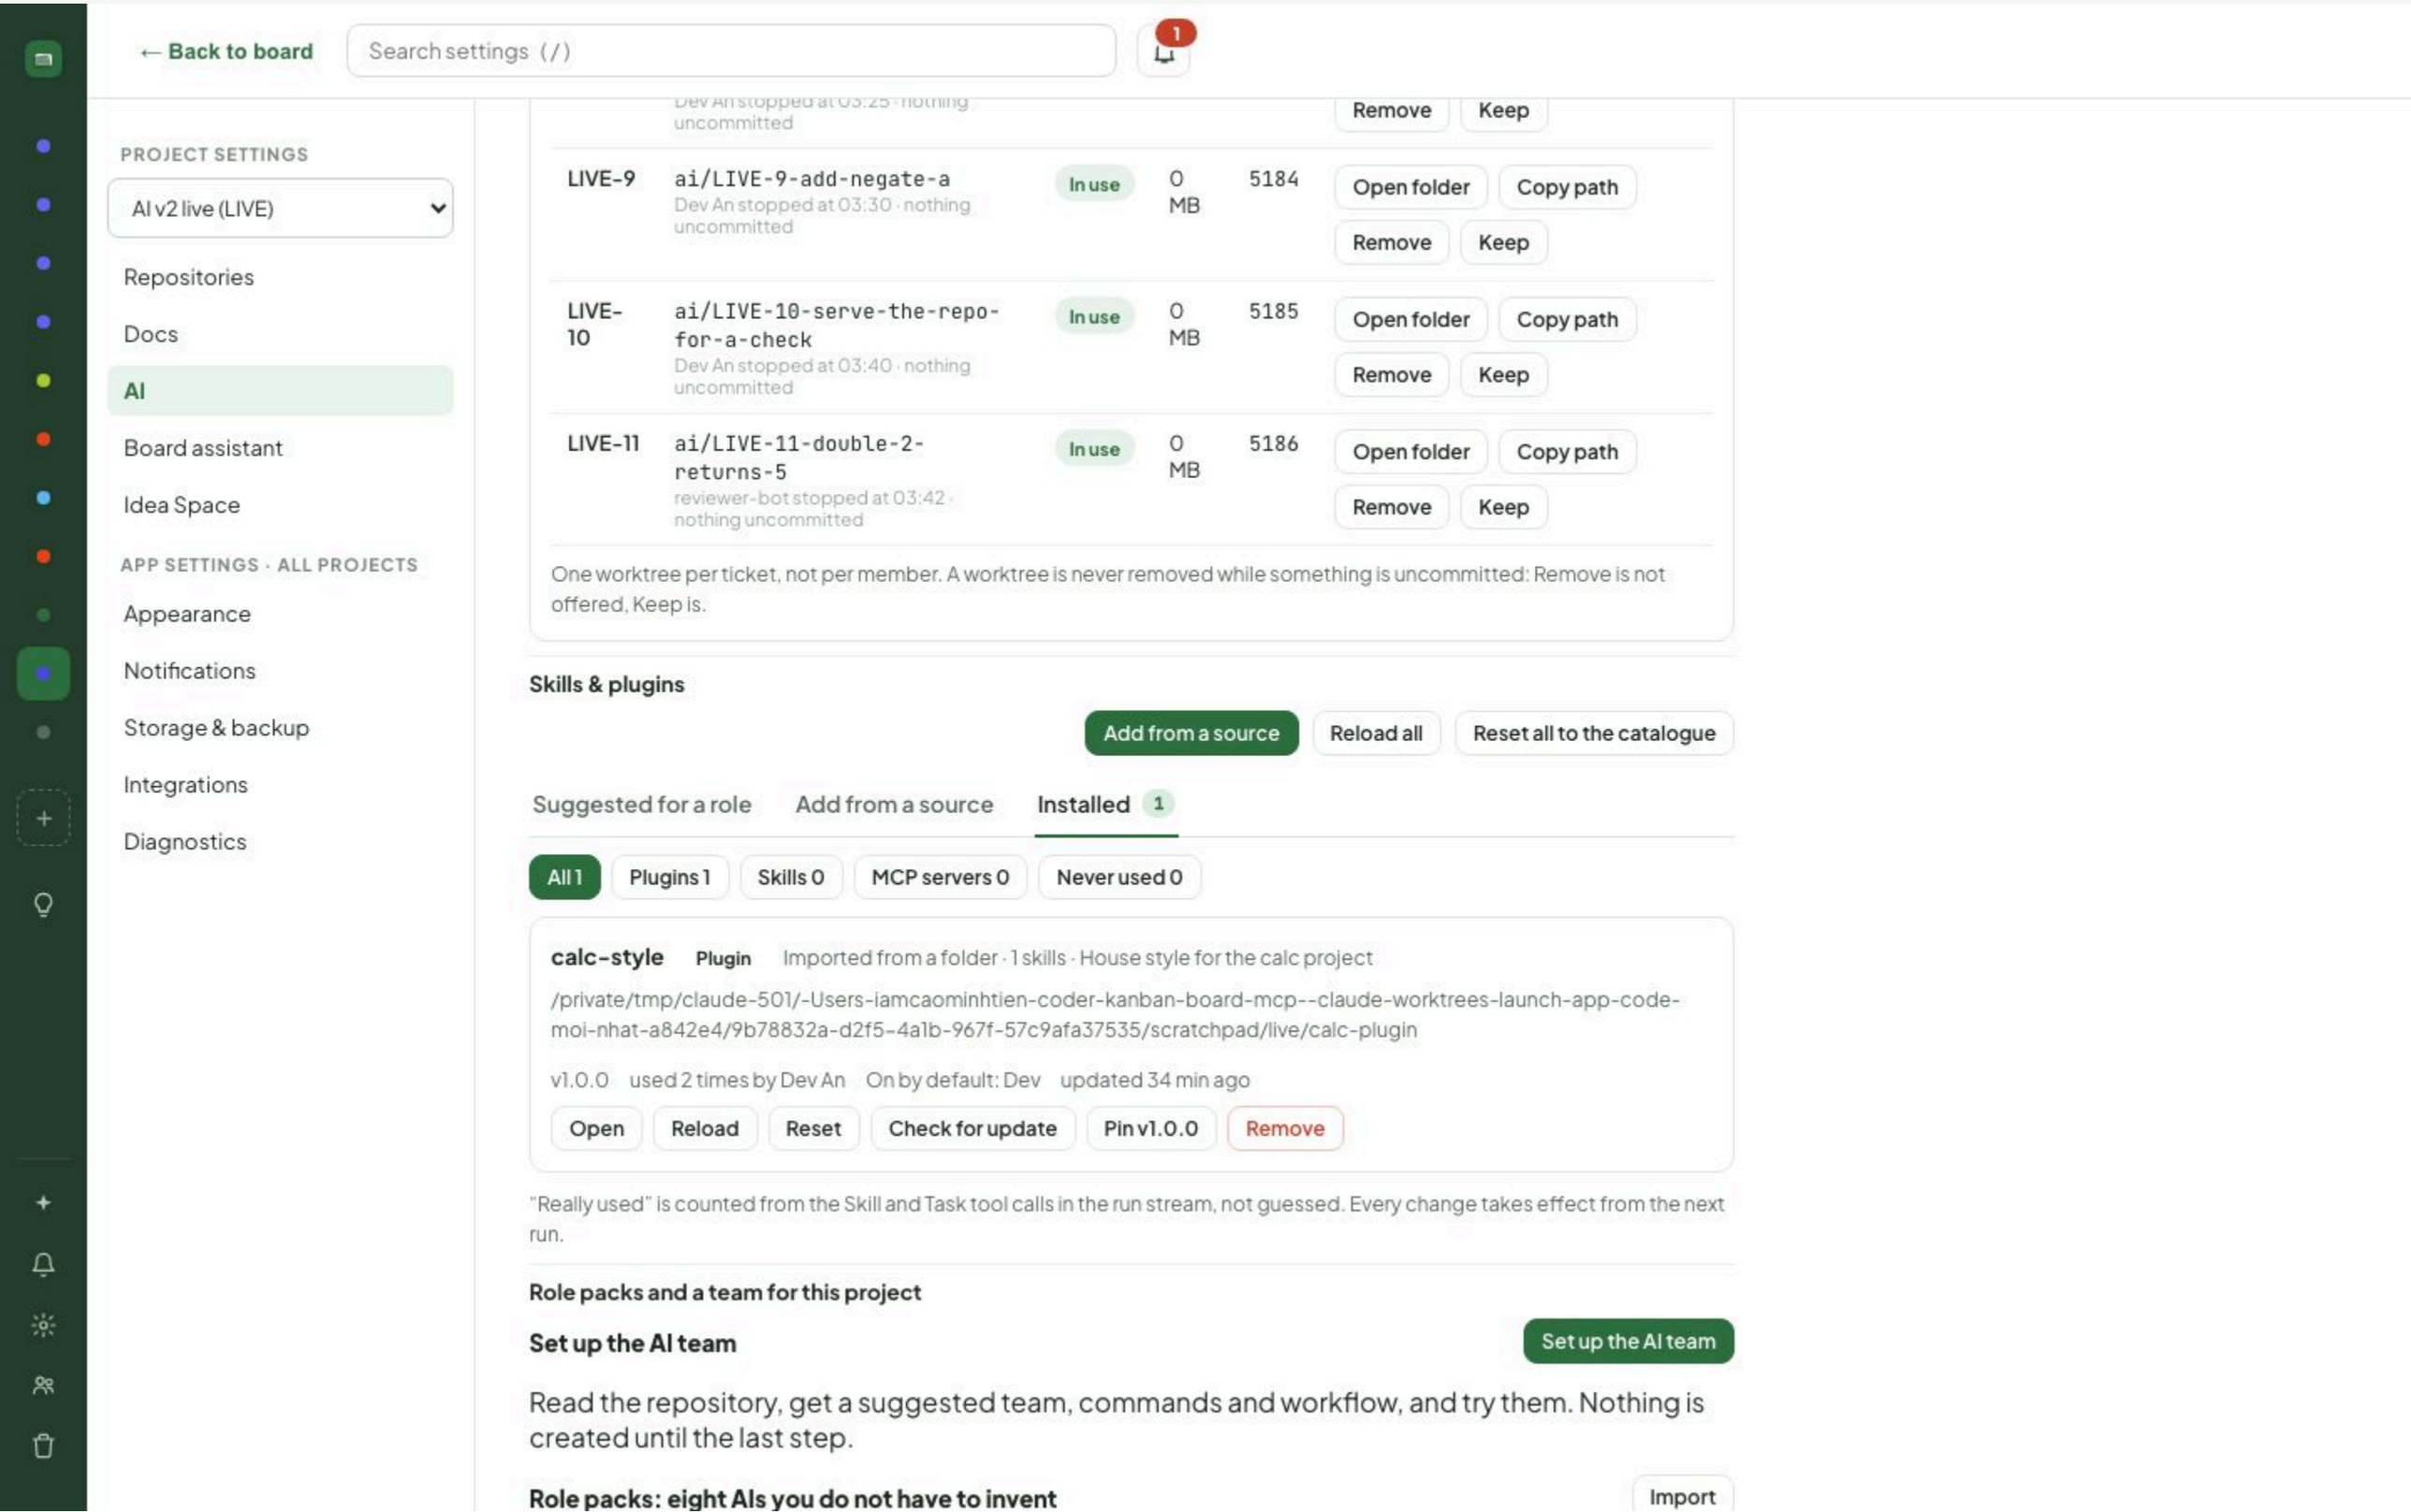

The knowledge base, with no embeddings

- A PDF of release rules, read into text, summarised and given keywords by Haiku, searched with BM25.
- A Dev asked to write the release note found it with the knowledge tool and followed it: codename PELICAN-7.

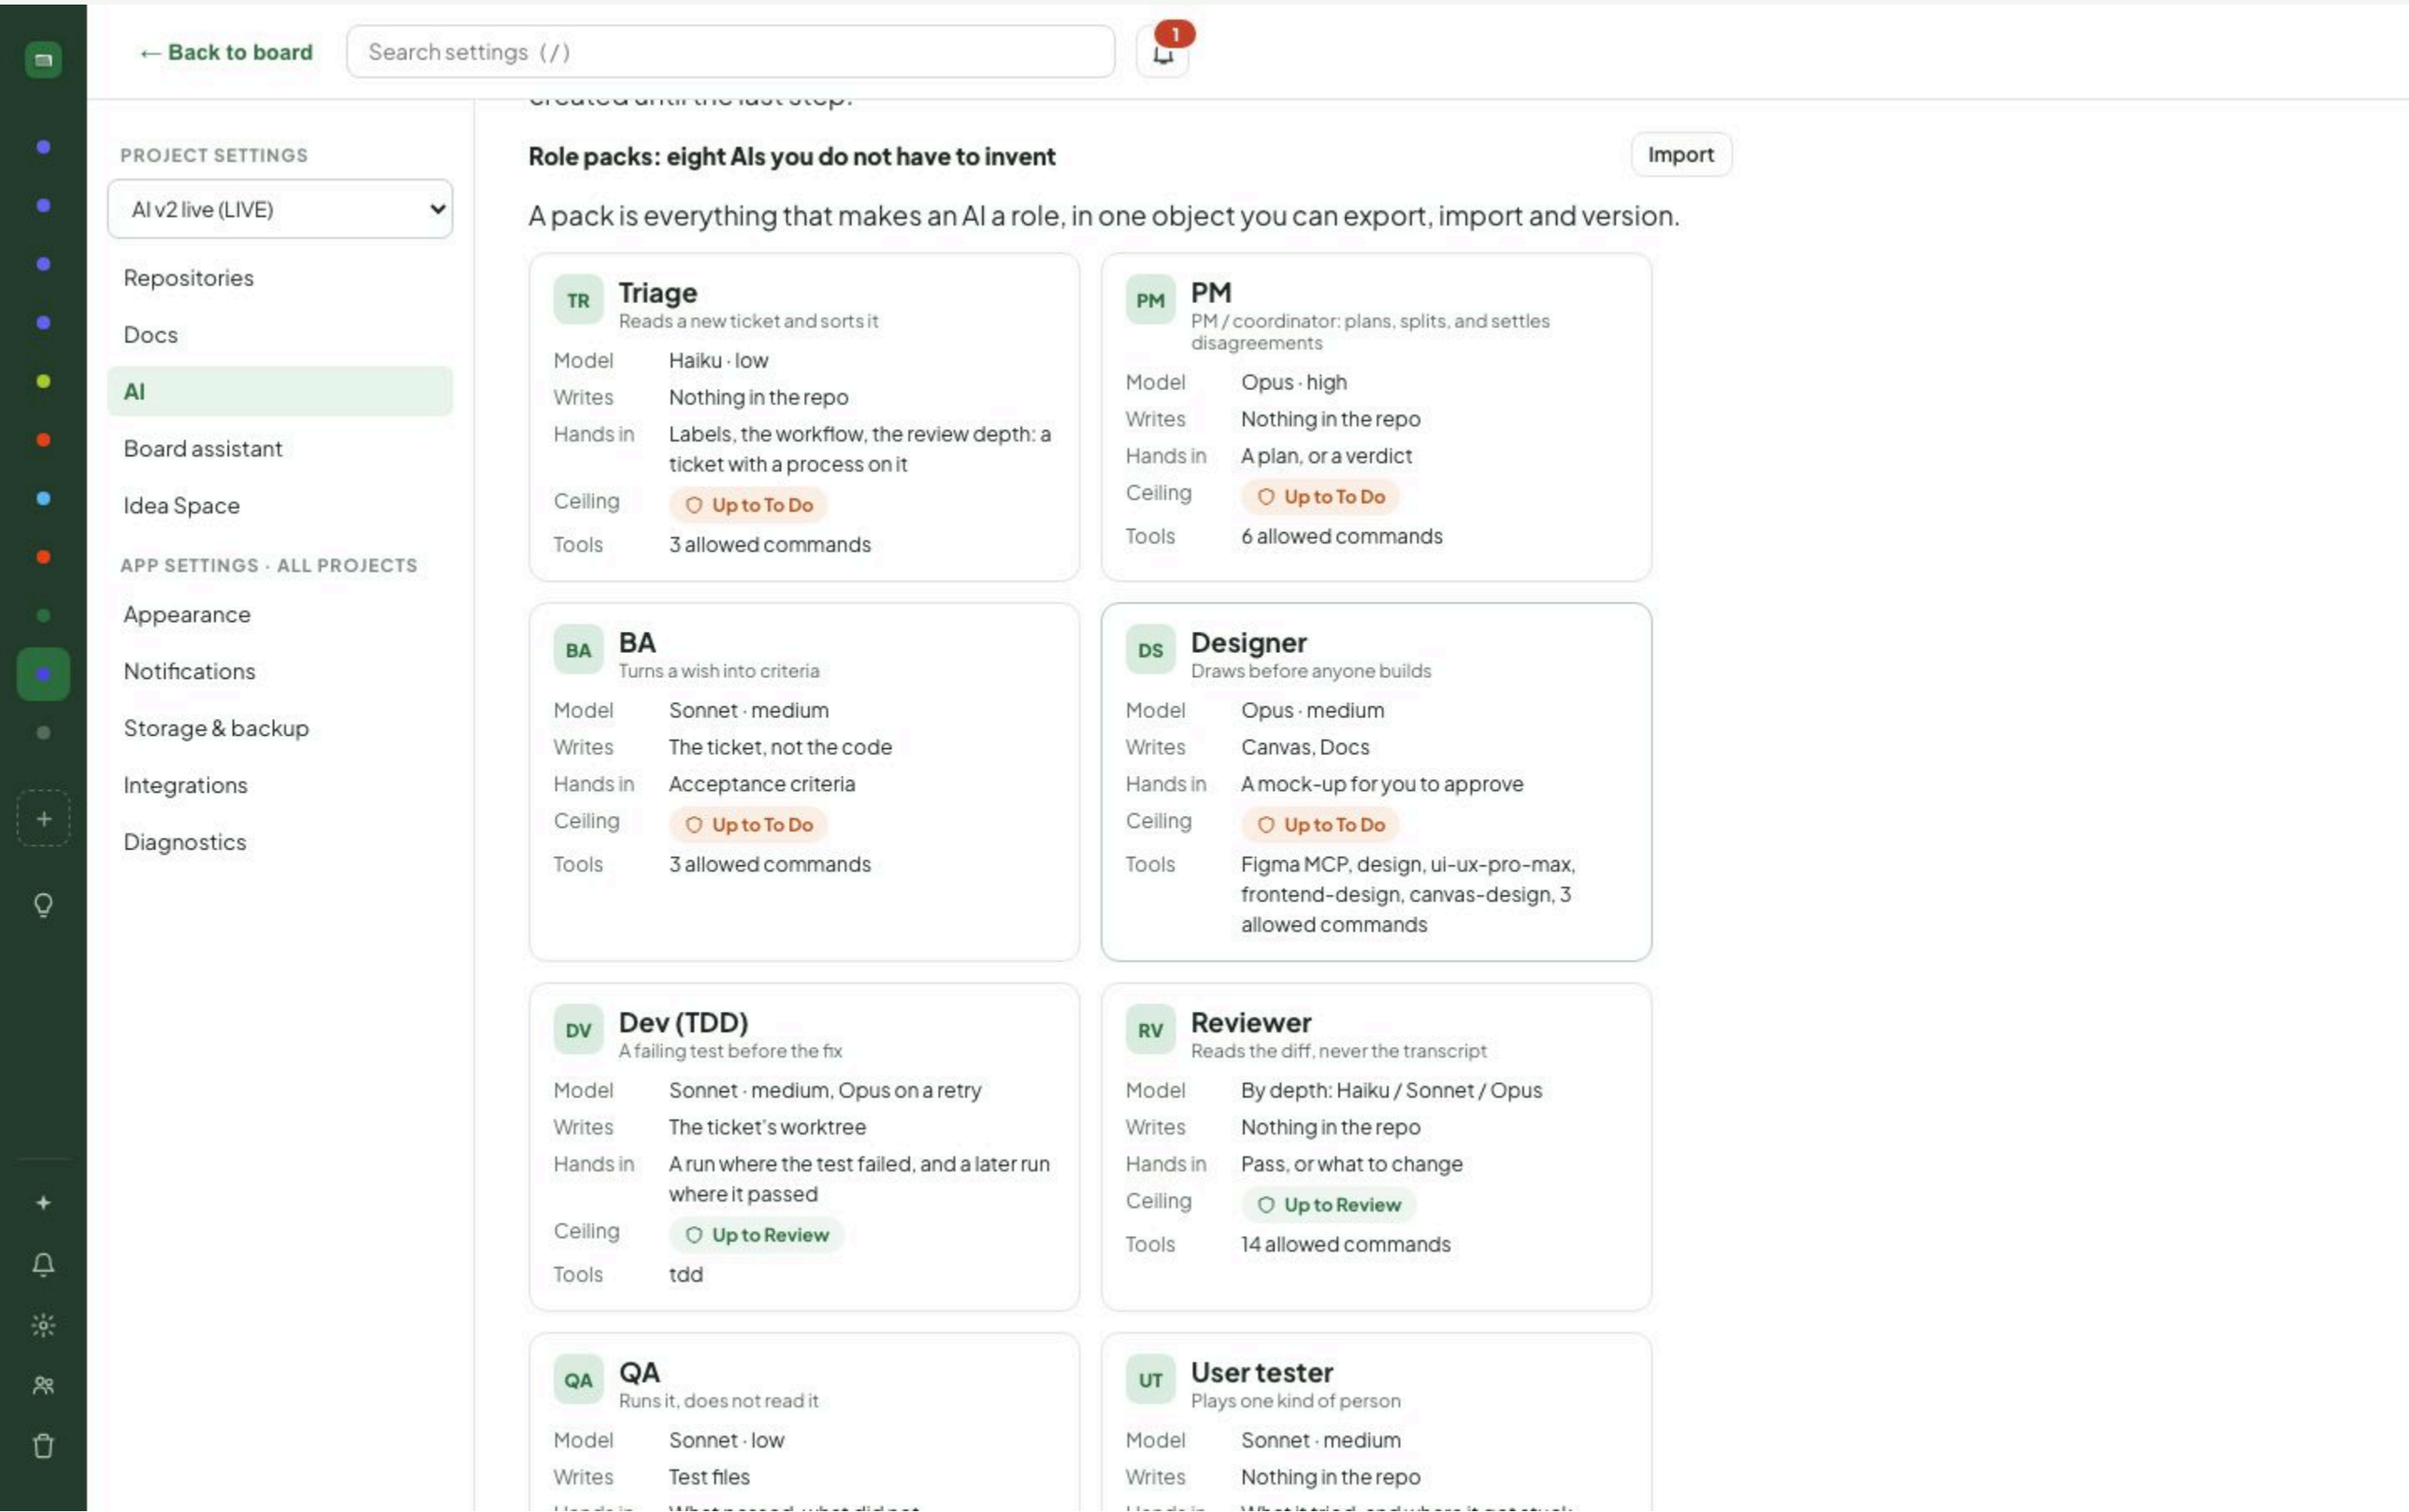

Skills and plugins, loaded per run

- A plugin added from a folder for the Dev role is loaded with --plugin-dir for each run, never written into the repo.
- Its skill was used by the Dev, and the board counted it from the stream.

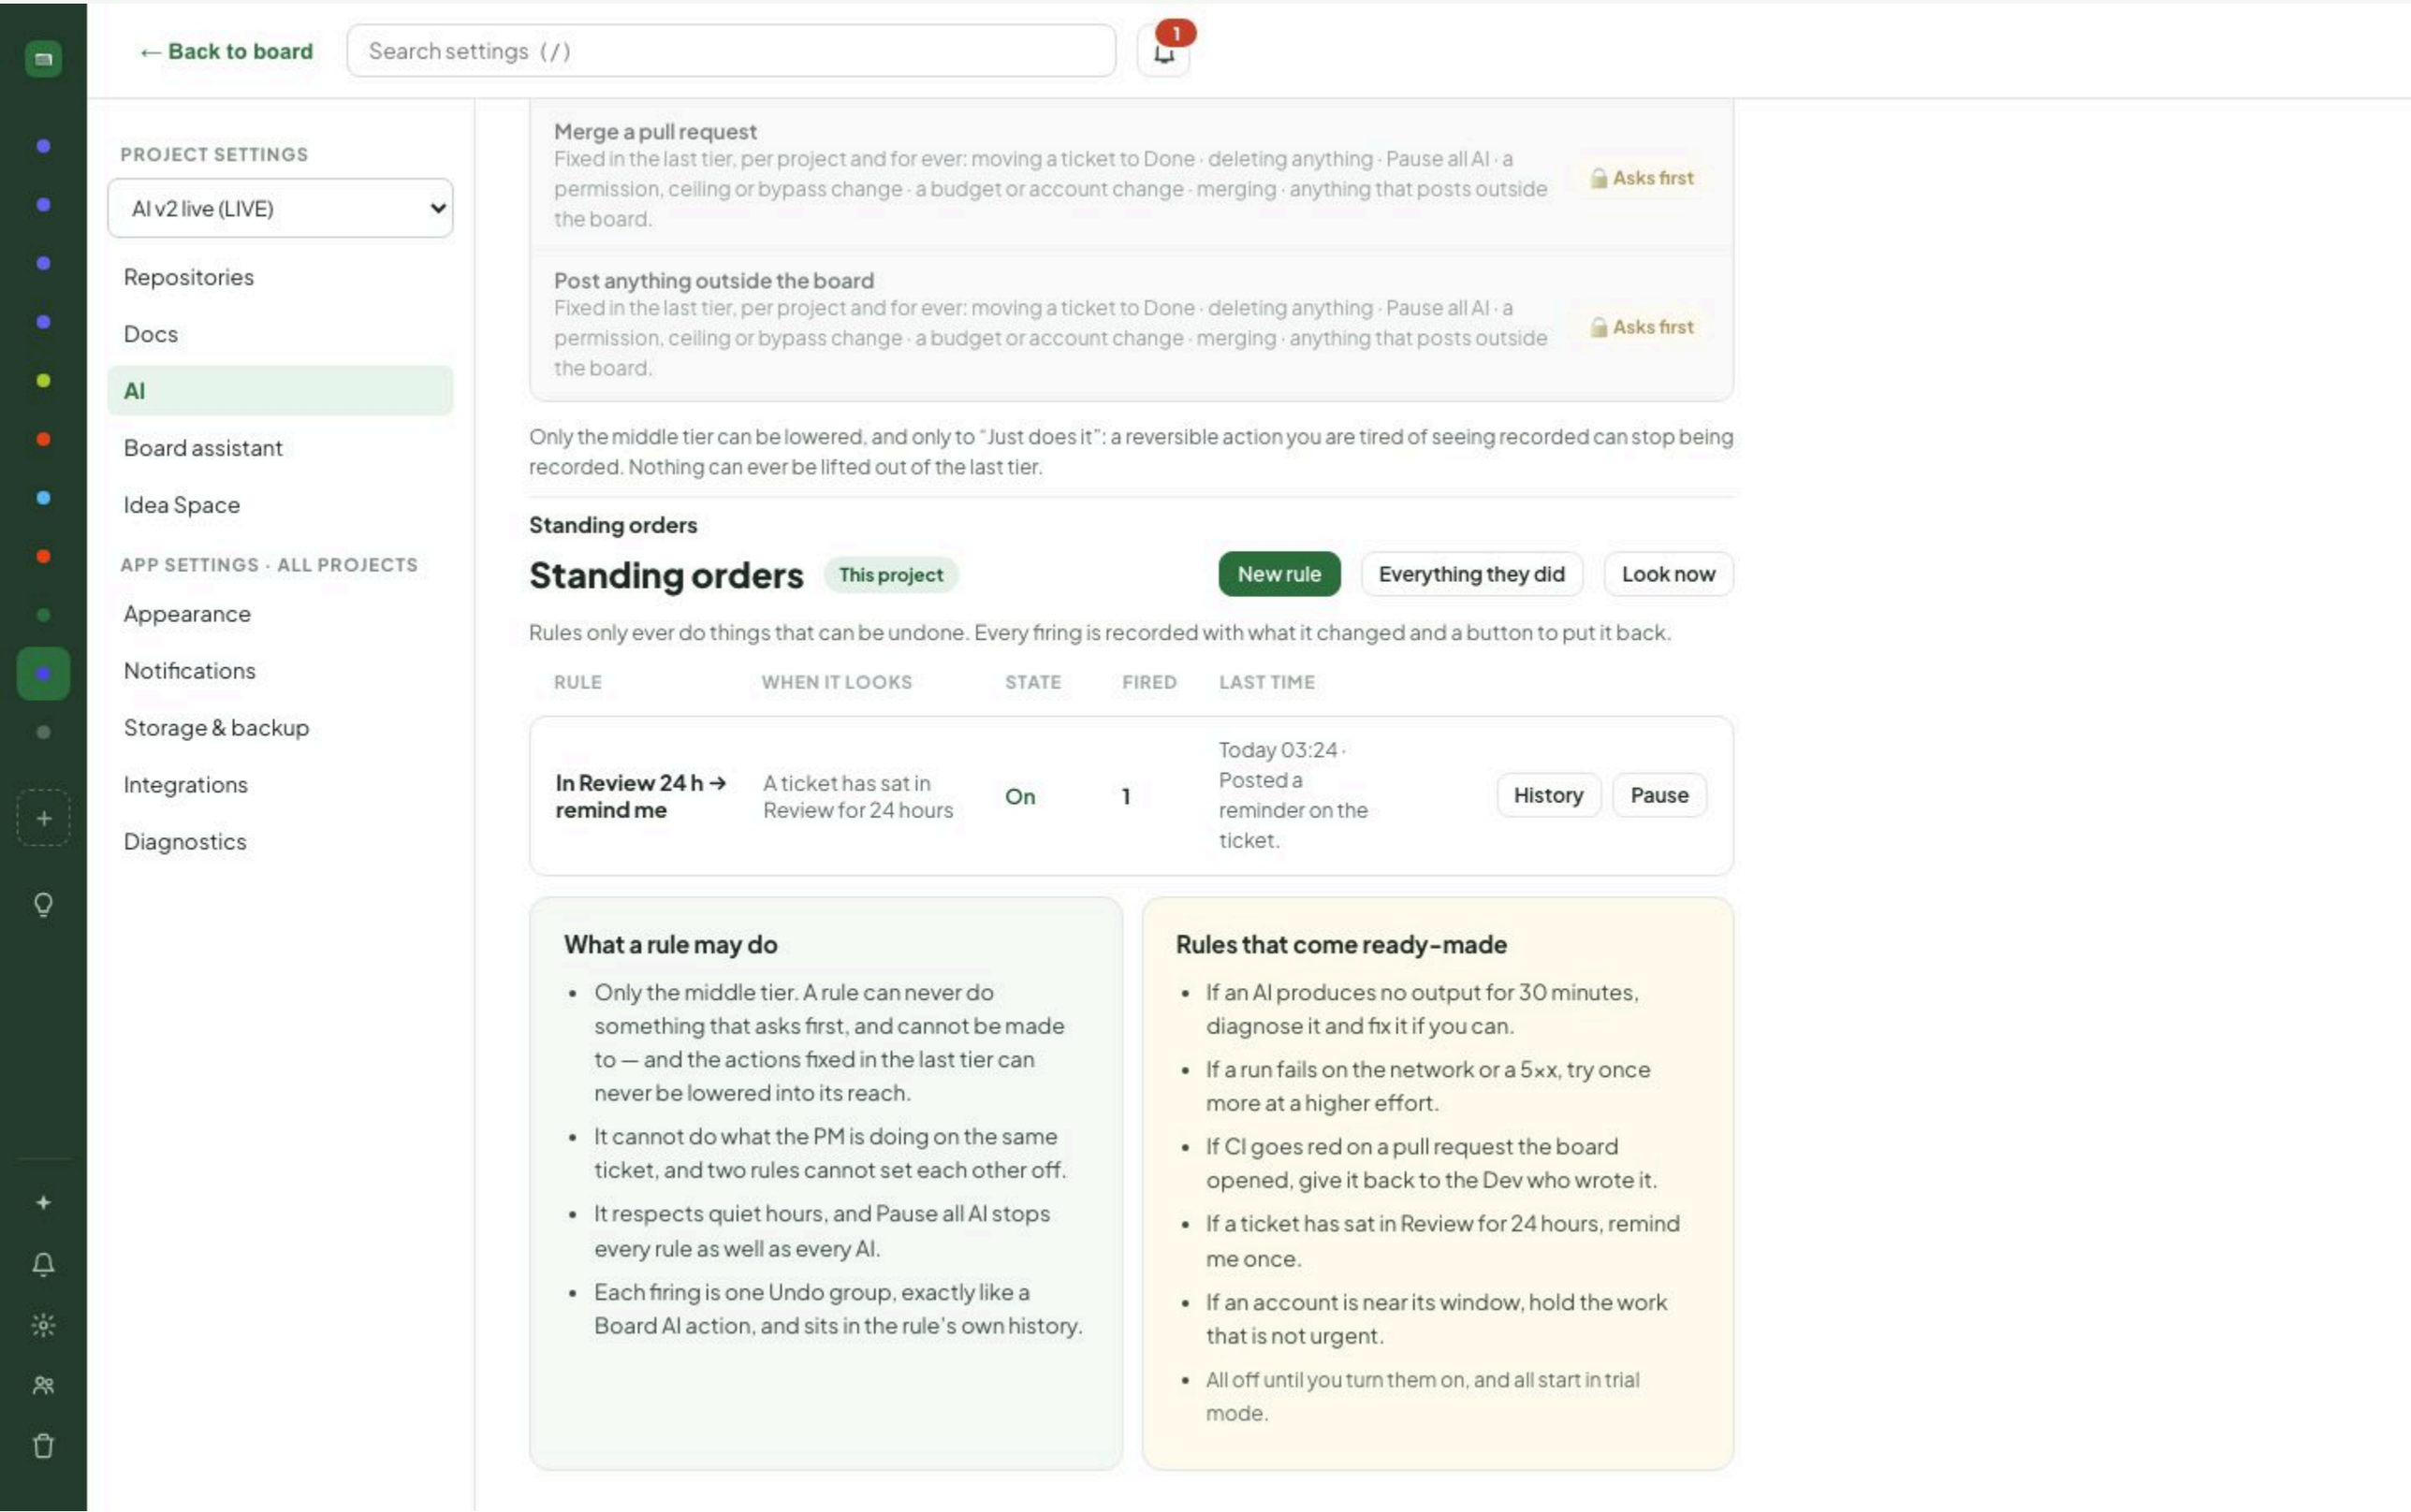

Eight role packs

- Triage, PM, BA, Designer, Dev (TDD), Reviewer, QA and User tester, each with its model, tools and ceiling.
- The members of this project were made from them.

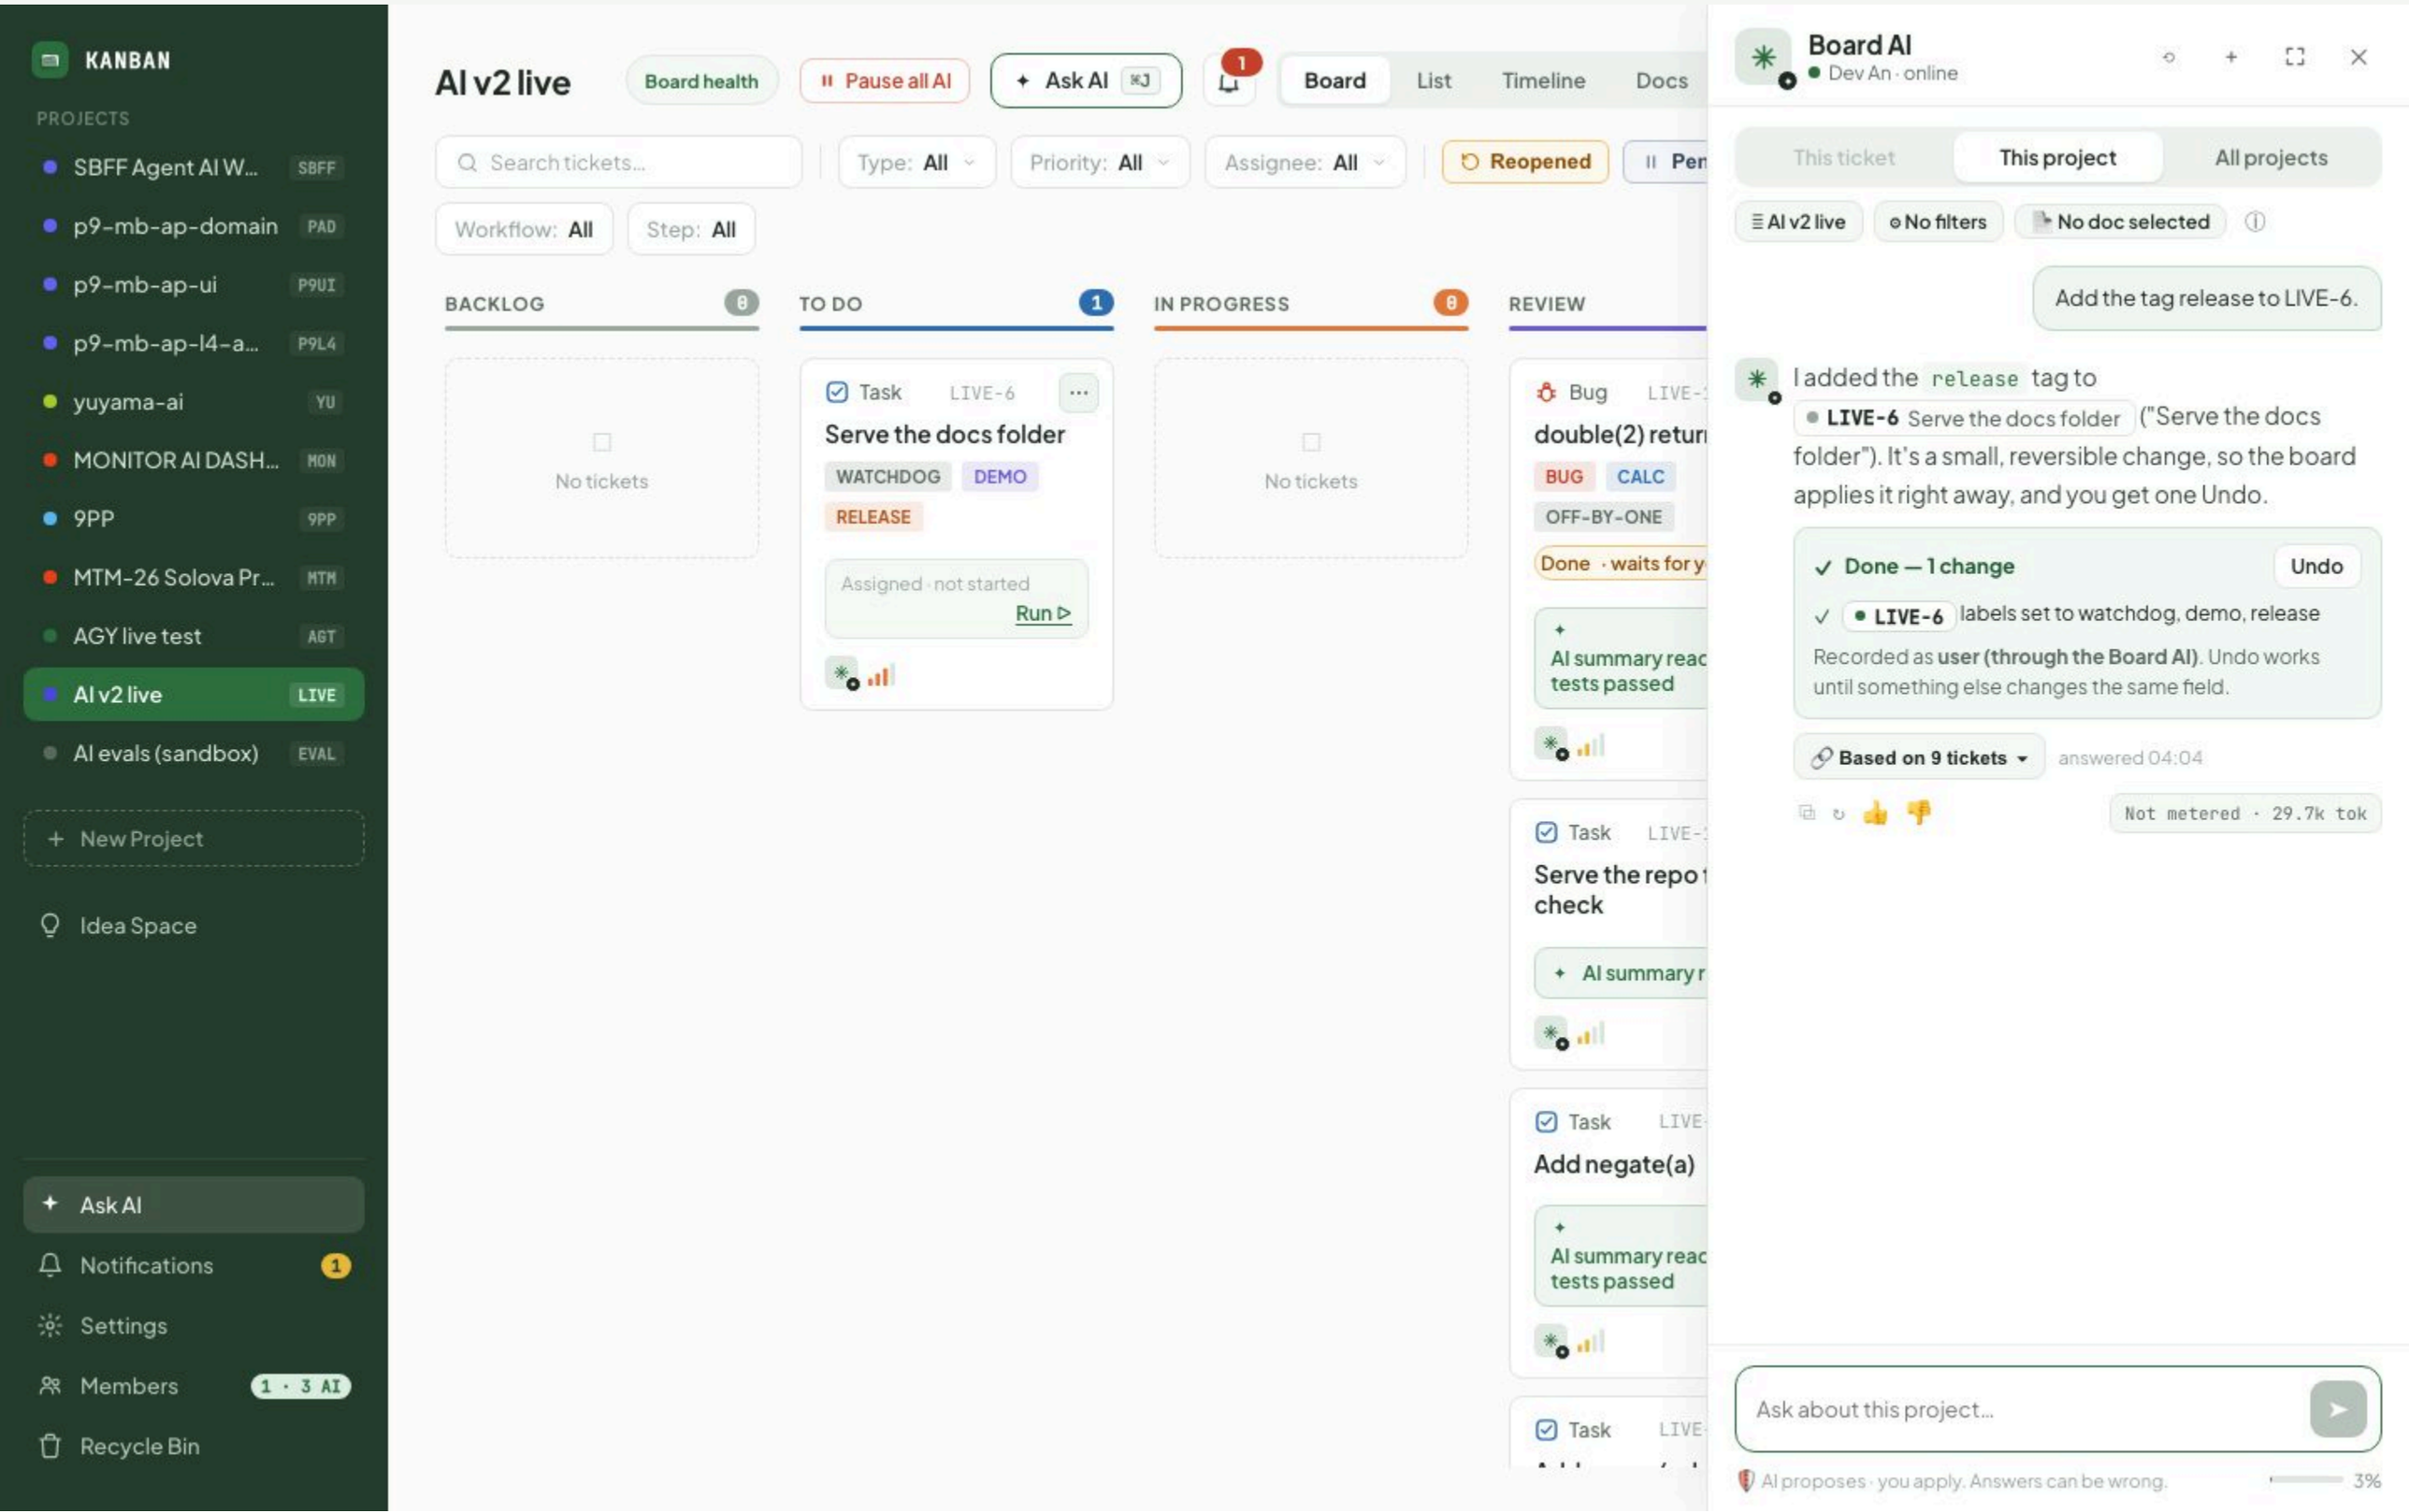

Standing orders, tried before they act

- A rule in your words becomes a rule you can read; it runs in trial first and only writes what it would have done.
- Turned on, it reminded on LIVE-1 once, and its Undo took the comment back.

The Board AI acts as you, by risk tier

- A small, reversible change is done at once, with one Undo: the label is on the ticket before you read the answer.
- On Claude Code it looks things up with its tools; a change goes through its answer so the board can apply the tier.

Done and bulk changes ask first

- Four tickets, and Done: nothing moved. The card says why and waits for your yes.
